THE ARCHITECT AND CONTRACT REPORTER. A JOURNAL OF ART, CIVIL ENGINEERING & BUILDING.

THE WEEK.

AFTER the resolutions adopted at the special meeting of the London County Council on Monday, the Works Department is not likely to cause much loss to the people of London, or at least until the so-called "Progressives" can once more become omnipotent. The susceptibilities of that party are not wounded, for the Works Department will continue to exist, although the Chairman says it is "practically extinct," but the members will enjoy a sort of sinecure. The first resolution adopted was as follows:—"That all works ordered by the Council to be carried out without the intervention of a contractor shall in future be carried out by the manager of the Works Department, who shall be responsible to the spending committee in the same way as a contractor would be, and that the finance committee shall have control of the finances of the department." It is not altogether clear how a manager can be made to bear an equal financial responsibility with a contractor, for the latter might have to expend a fortune in carrying out the conditions of a contract; but the intention, we suppose, is that the Council will look to the manager rather than to the Works Department, and if there are losses he runs a risk of dismissal. Through the next resolutions the ignoring of the Works Department will be extended:—"That any committee desiring to propose to the Council the carrying out of any works without the intervention of a contractor shall, in the first instance, obtain an estimate from the proper officer and then refer such estimate to the manager of the Works Department for his examination and report before reporting to the Council," and "That the works manager shall be responsible to the spending committee, and the committee shall report from time to time to the Council." The manager will, no doubt, have a difficult rôle to perform, for while he is supposed to be the officer of a department without power, he will have to carry out the demands of departments who are not supposed to have any acquaintance with works. The question must also arise whether, if one department can be carried on with an honorary committee, is it not also feasible, as well as economical, to adopt similar arrangements elsewhere? The extravagance and mismanagement of the Works Department may, therefore, eventually bring compensation by the simplifying of the whole system of administration in the Council. The legitimate contractor is also to have a chance, for such alterations can be introduced in "the conditions of contract as will insure fair and just treatment of contractors, and to remove the objections which many of the best London firms have to tender for the Council's work." It will, therefore, be possible to carry out municipal works on a honest basis, and without the necessity of sham profit and loss accounts or supplies to make up for deficiencies which dare not be revealed.

AN esplanade, promenade, or sea-wall in a watering-place is generally open for public traffic, and to that extent resembles a high road, but as carriage traffic is often disallowed, and the promenade is not necessarily in direct communication with main roads, there is some difference between it and a highway. The class in which one of these frontages is to be placed becomes important, especially when payment has to be made for repairs which become necessary by the encroachment of the sea. A case of the

kind has arisen at Sandgate. Part of the way known as the Esplanade, with its groyne, was washed away, and the reconstruction cost 6,000*l*. The local authorities claimed the amount from the County Council of Kent. The dispute was referred to an arbitrator appointed by the Local Government Board. He decided against the County Council for the larger part of the claim, the exception being a groyne and work in connection with it, which cost 1,500*l*. The County Council appealed. The Master of the Rolls, in giving judgment against the award, said under the Highway Acts it was never intended that the liability imposed upon the county to contribute towards the maintenance of main roads should include a liability to do so in the case of an esplanade or sea-wall such as the one which formed the subject of this arbitration. The promenade was built for the benefit of the inhabitants of the watering-place and as an attraction to visitors, and was not a "highway" for the use of the county generally. When the road was made a main road the sea had not encroached to the same extent as now, which rendered the question on whom lay the liability to repair damage done by storms from time to time a very serious one. In his opinion the local authority had no claim whatever against the County Council or those who happened to be on it for any contribution towards the expenses that had been incurred in repairs. The Lords Justices were of the same opinion. Judgment was therefore entered for the County Council of Kent, with costs.

IT is difficult to make paintings at a cheap rate which will combine accuracy of portraiture and picturesqueness. Mr. J. S. PHIPPS wished to have a sort of hunting scene at Burnham Beeches, and a coaching picture. One was to cost 150 guineas and the other 50 guineas. Instead of dealing directly with an artist or artists, he gave the commission to Messrs. M'QUEEN, of the Haymarket. They employed Mr. HARRINGTON BIRD to paint the landscape, hounds and horses, and Mr. SPENCELAYH for the portraits. When the work was completed Mr. PHIPPS was not satisfied, for some of the figures were not, he considered, as accurate as he had anticipated. He therefore declined to take the pictures, and it became necessary to have recourse to the Law Courts. At the trial on Wednesday, Mr. BIRD said he showed defendant the pictures, and made alterations to please him. Mr. SPENCELAYH also said the portraits were properly painted, but in the case of small portraits it was impossible to avoid making them appear hard if details must be introduced. Mr. PHIPPS, the defendant, said it was arranged that the works were to be subject to his approval. Expert evidence was given on both sides, but the jury found a verdict for the full amount which was claimed. It is satisfactory to find a special jury showing so much good sense. To admit the plea that an artist must always please his patron would be fatal to art. Art is, or should be, the genuine expression of the artist's thought, and to compel him at his peril to rival the photograph in a mechanical or chemical reflection of a face would be degrading. The case suggests how little is known about the aims of painters among people who are believed to be educated. At the same time, it is unfortunate to find artists ready to produce portraits after two sittings of photographs are lent for their use.

CANTERBURY CATHEDRAL.

LAST week England was celebrating a reign which has lasted during sixty years. To-day a great many of the inhabitants may be said to commence the celebration of another reign which has existed for more than twenty times sixty years, and as yet exhibits no signs of decay. The visit of the bishops to Ebbs Fleet, the spot in the Isle of Thanet on which St. AUGUSTINE landed in 597, is a recognition of what may be called the beginning in an official sense of the Church in England. For the history of the primatial see of Canterbury can be traced from the time when St. AUGUSTINE took his seat as archbishop. There were already Christians in the city. According to BEDE, two churches were erected in Canterbury "whilst the Romans inhabited Britain," and it is supposed the still existing St. Martin's is one of them. Moreover, BERTHA, the wife of the Kentish King ETHELBERT, was a French princess, who on her marriage had stipulated for freedom to worship according to the Christian rites. It was in reliance on her power that AUGUSTINE was sent with forty Italian and Gallic monks by St. GREGORY THE GREAT to convert the Anglo-Saxons.

When the late Mr. STREET introduced a figure of St. GREGORY in the new porch of Bristol Cathedral, there was an outcry which amazed not only the architect and the cathedral authorities, but everyone who was acquainted with ecclesiastical history. For that Pope was the first man who was possessed of a belief in the future of the Anglo-Saxon race. From the moment when he made his memorable pun in the Roman slave market, and described the British children exposed for sale as angels rather than Angles, until his last days, Britain exercised a fascination over him which he never cared to conceal. His letters prove that every advance made by his representatives gave him exquisite pleasure. It was with a prophetic eye he fixed his gaze on the remote island amidst the western seas. It is manifest that AUGUSTINE and his followers were unable to understand the Pope's enthusiasm for so barbarous a race. The monks had not travelled far from Rome before they became alarmed at the perils awaiting them, and sought permission to abandon the enterprise. GREGORY proved he was entitled to be called "Servus servorum Domini," for instead of threats he appealed in the humblest way to the missionaries, imploring them to continue their journey. Evidently he was alarmed that his pet project would not be realised in his lifetime. Afterwards, when a footing was gained in Britain and the prospects of the Church were promising, we find AUGUSTINE, who apparently was one of those formalists who must have authority in writing for everything, demanding solutions of various questions which seemed hardly to belong to an infant Church. In reply GREGORY again shows his large heartedness, his desire to see the spirit rather than the letter of the law prevail, his tolerance of departures from ritual by the new converts. He went so far as to oppose the destruction of heathen temples, and suggested that it was preferable to purify them and convert them into Christian churches—advice which, if generally followed, would have preserved many relics of antiquity.

According to tradition, AUGUSTINE and his monks first settled in a street afterwards known as the Stable Gate, in the parish of St. Alphage, Canterbury. Apparently the bishops, or rather archbishops, lived for more than a couple of centuries with the monks in community. It is not related that AUGUSTINE built a cathedral, although full liberty was given to build and repair churches in all places. He is supposed to have employed for that purpose a basilican building which stood on the same site as the present cathedral. It is sometimes said the church of St. Martin was the original cathedral, but as it was soon found to be too small to accommodate the crowds of converts, King ETHELBERT assigned his palace to AUGUSTINE, who transformed it into a church, and dedicated it to OUR SAVIOUR. But it is impossible now to discriminate between statements which were merely traditional and those which are worth accepting as evidence. The Christian Church of Canterbury was in its early days enriched through the generosity of converts, not only with gifts in money but with landed estates, and, following the usual custom, a large proportion of the wealth would be expected to be devoted to building.

Yet there is no record of any building existing which would be worthy of an archdiocese. There is a mention of the Canterbury Cathedral in the tenth century, but it is puzzling. When ODO was transferred from Winchester in 941 he is said to have found the cathedral in an unsafe condition, for the roof was broken and the walls were falling. He at once commenced restoration. But when it is related in the same account that during the three years the works were in progress ODO's prayers were heard, and no rain fell in Canterbury, we seem to have no more than a pious legend to guide us, which may be figurative in its expression, and was not intended to serve as an illustration of architectural history. In 1011 there is a record which unfortunately seems to be probable. The Danes or Northmen are said to have attacked the church and set fire to it. The lead with which the roof was covered was melted and fell on the monks who found a refuge in the building. Those who endeavoured to rush forth were thrust back or slain. CANUTE, it is believed, endeavoured to make compensation for the misdeeds of his fellow rovers by restoring the cathedral, and gave back the revenues of which the monks were deprived during the wars. In those records it is assumed that the building which suffered was the basilica in which AUGUSTINE officiated.

A description by EADMER suggests there was a resemblance between it and some of the primitive Roman churches. The part used by worshippers was divided into a nave and aisles. At the extreme east end was an altar of unhewn stone which served as a shrine for the remains of St. WILFRID. Nearer to the congregation was the high altar at which service was celebrated daily. This part of the building was at a higher level than the nave. A space surrounded by a partition was assigned to the singers in the nave. Near the south entrance was a chapel which was sometimes used as a sort of law court. Against the west wall was placed the archbishop's chair, made of large stones set in mortar. There were also various altars and chapels in the building. The undercroft or crypt was formed with a vaulted roof, and extended beneath the eastern part of the building.

When WILLIAM THE CONQUEROR succeeded in his enterprise and was eager to have England organised, he fixed on LANFRANC the Lombard as the most capable ecclesiastic to rule in Canterbury. He was a type of the advanced Mediæval scholastic, and had served as professor, disputant, ambassador and abbot. It was with difficulty he could be persuaded to accept the archiepiscopal mitre. When he arrived at Canterbury the state of the cathedral made him despair of bringing it into a condition becoming the foremost church of the kingdom. The extent of his restorations is not clear from the record, and while some suppose that LANFRANC's operations were restricted to the superstructure, there are others who conclude that the crypt was also reconstructed by him, and that he created a new building. But as LANFRANC is said to have occupied no more than seven years with his works, it is difficult to realise how so much could be accomplished in so short a period.

According to GERVASE, the new church was marked in the centre by a tower supported by four immense piers. It was known as the "Angel Steeple," from a figure on one of the pinnacles. The nave was westward of the tower, and the roof was supported by eight pillars. Under the tower was the altar. Across the building was a rood-beam. In the south transept the organ was placed. In the north were tombs of some of the archbishops. There was a pillar in the middle of the transept, which was afterwards removed to afford space for the altar of St. THOMAS A BECKET. The crypt was approached by several steps.

ANSELM succeeded LANFRANC. For a time he made it a practice to expend his revenues upon the choir. By his orders the then-existing choir was removed, and under the superintendence of Prior ERNULPH another was commenced which surpassed all others in England. It was, however, completed by Prior CONRADE, with whose name it was associated in the chronicles. ANSELM did not live to see the beautiful choir in all its glory. It was dedicated during the episcopacy of WILLIAM CORBOIL, in the presence of the king and queen and DAVID OF SCOTLAND.

On December 29, 1170, the great tragedy was enacted which will make not only the cathedral but Canterbury

unforgettable as long as the world lasts. The tenure of office by THOMAS A BECKET was too precarious to allow him to exhibit himself as a lover of building. He did not enrich the cathedral. After the archbishop's murder the cathedral was closed by order of the Pope for a year or two. A fire which occurred in 1174 appeared to be a punishment

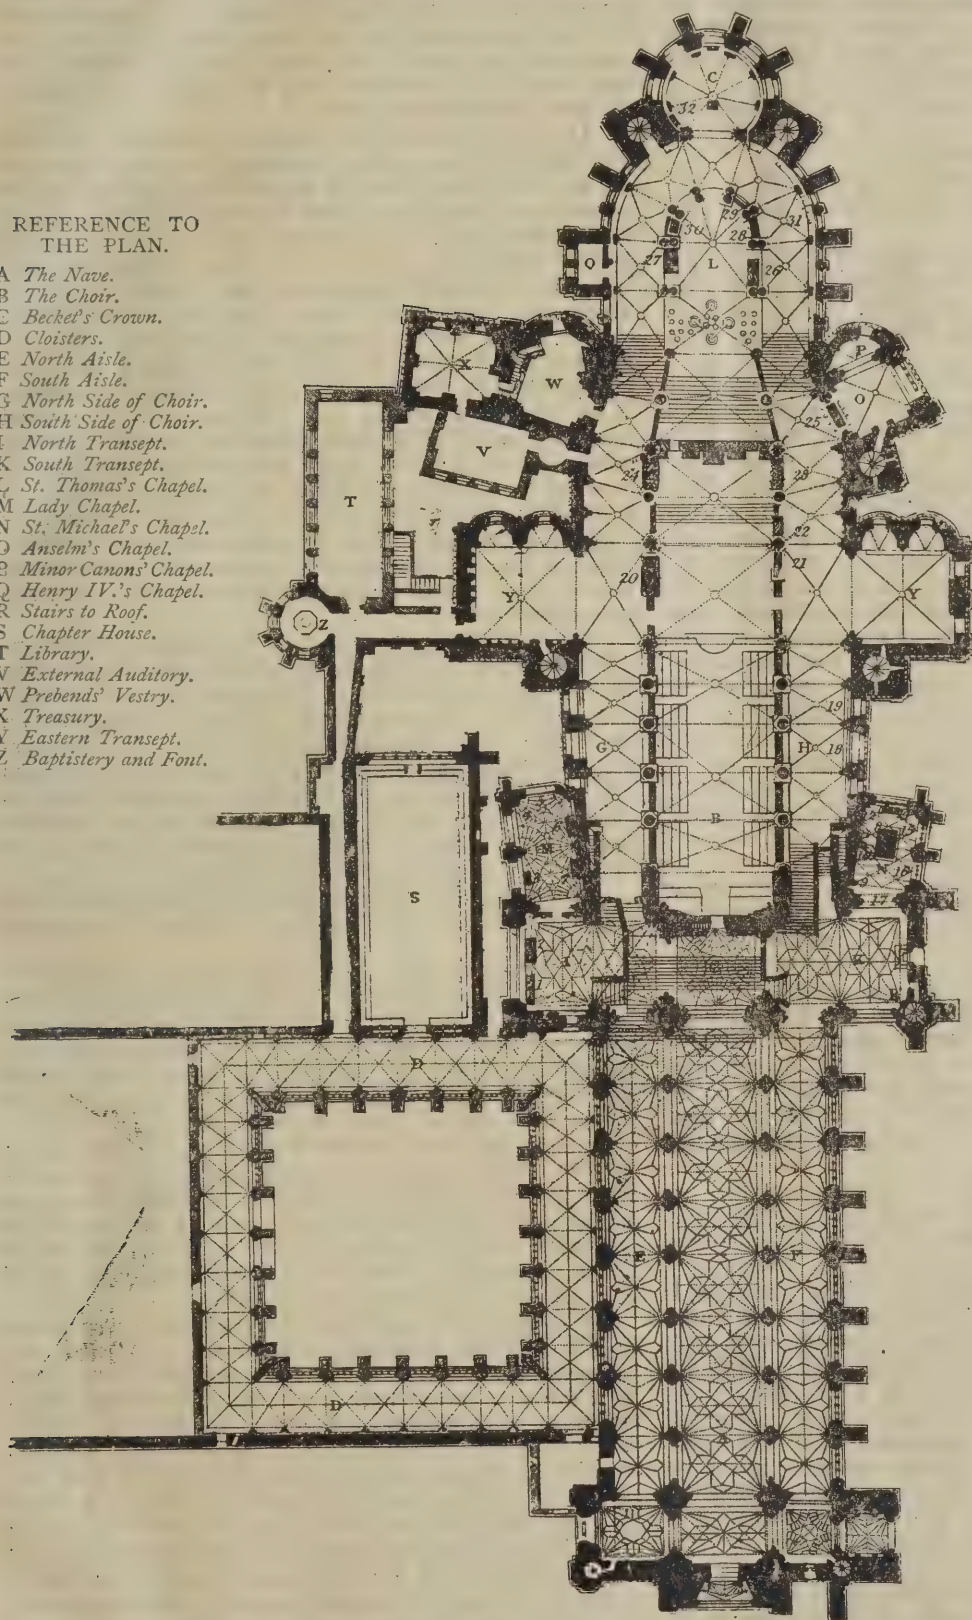

called WILLIAM. He was pressed to expedition by the monks, and in a year or two the choir rejoiced all eyes. The Englishman is also credited with the eastern transept, Trinity Chapel, Becket's Crown and the crypts beneath. With WILLIAM'S work we come to the end of the Norman style. There is much variety to be seen in the treatment,

for the sacrilege of which the cathedral was the scene. The new choir was destroyed. But no time was lost before commencing restoration. WILLIAM OF SENS was appointed architect, and in 1175 the masons were at work under his direction. He was engaged during five years, but a fall from a scaffold compelled him to return to France. He was succeeded by a little Englishman who was also

and indications are not wanting that a new style was about to appear. But the great interest of the early work is historical. The BECKET tragedy made the cathedral unique as a place of pilgrimage, and, as good often arises out of evil, a period of financial prosperity followed in which all the religious of Canterbury were sharers.

(To be continued.)

AIDS TO THE EXTENSION OF ELECTRIC LIGHTING.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

THERE is now a great movement amongst the electric-lighting supply companies and corporations in the direction of the extension of electric lighting, chiefly amongst poorer consumers. The means by which this is being carried out are as follows:—

1. The substantial reduction in price to long-hour consumers.
2. The free wiring of premises.
3. The use of automatic (penny in slot) meters.
4. The supply of lamps free of charge, or guarantee of the life of lamps.

These four points strike at the root of the difficulty in inducing the public to use the electric light. The first point has already been dealt with very fully in this Journal in some of my previous articles, and the remaining three points will now be dealt with.

Free Wiring of Premises.—The cost of installing electric light in houses, &c., has always been the great deterrent to the majority. The intending consumer, especially the middle-class one, looks at the matter from an eminently practical point of view. He usually has gas-fittings, which are useless if he installs the electric light, and the high cost of a good electric-light installation is more than he is prepared to pay. There is usually very little or no saving in the light bill claimed by the adoption of electric light, the benefit being on the score of cleanliness, less cost of painting and whitewashing, and saving of the damage to goods caused by gas. The small shopkeeper and householder thinks of the high capital outlay and underrates the benefit of electric lighting because it is indefinite. The usual result is that the wiring canvasser finds, after wasting much time and preparing estimates, that the consumer thinks he will have to wait a little longer before incurring the outlay, as he really cannot afford the expense just now. In fact, the money is usually worth more to him, or he thinks it is, than a pure light.

Now, if this consumer is approached in a different way he will, no doubt, adopt electric light. If a hire-purchase system extending over, say, five years is proposed, there is no doubt the consumer is secured. This system was tried, and is now being used in Galway (Ireland) with a marked success. The system was a three years' one; 5 per cent. on the capital outstanding is charged quarterly in addition to the twelve instalments. This satisfies the supply company and the consumer, who usually prefers this method of payment, because his money is worth more than 5 per cent. to him; in fact, the terms are too lenient, as many rich people take the system up.

A somewhat similar system has been proposed by the writer for two Irish towns with which he is connected as consulting engineer, and the matter shows every prospect of being taken up extensively. The system is as follows:—

Installations will be undertaken for those who desire it under the following terms:—A charge of 6 per cent. on the cost of the installation will be made per annum for interest on capital and maintenance of installation in good repair, and a further charge of 5 per cent. as a minimum will be made for the sinking fund per annum. The wiring will become the property of the consumer when the whole amount has been paid off. A greater amount than 5 per cent. can be paid off in any year or years, enabling the amount to be paid off sooner. The wiring will be kept in repair by the undertaker, excluding breakage due to wilful damage or carelessness.

There is another method of charging for wiring which has been pushed by large syndicates in various towns during the last year or so. This consists in putting up fittings for consumers, making no charge, but increasing the price of electricity to them by a small amount, say $\frac{3}{4}$ d. per unit, which amount becomes the property of the syndicate. The fittings never become the consumers' property, but always remain the property of the syndicate or their assignees. This has been taken up with great eagerness by the poorer consumers and has already proved a success, as these consumers use a considerable amount of electricity per lamp installed. One syndicate has introduced

automatic meters (penny in slot) in connection with these systems.

These poorer consumers are so desirable that in some cases the supply companies or corporations have allowed the $\frac{3}{4}$ d. per unit off the usual price, the consumer obtaining his supply at the standard rate. Although there is no doubt as to the success of these latter (increased cost per unit) systems, they are obviously unfair to the best consumers, as the payment for fittings bears no proportion to their cost but to the amount they are used, which penalises the most desirable consumers.

The use of prepayment meters, whether connected with free wiring or not, is to be encouraged for several reasons. In the first place, there is no difficulty in collecting the accounts, as the current is paid for before delivery; and in the second place, the payments are not felt by the poorer consumers, who, as a rule, object to large bills at unfrequent intervals, and prefer a system which uses their loose coins. Even the upper middle classes prefer such a system, as it prevents waste. An instance may be given of a case where the family goes away for the summer, leaving the servants in charge of the house, being allowed a weekly sum for expenses. The usual method is to cut off the light altogether, but with a prepayment meter the servants could have the light by paying for it out of their allowance. Many improvements will have to be made in automatic meters before they will be extensively adopted, as complaints have been made as to their reliability. There is, however, no reason why automatic meters should not be made perfectly reliable, and a few years' experience will suffice for this.

The remaining point is that of free lamps. The incandescent lamp is undoubtedly one of the chief annoyances to the consumer of electricity. They sometimes have a habit of failing after short use, and the cost of the lamp is then a loss. The same argument applies to incandescent gas-mantels, only with greater force, but still the fact remains that the cost of lamps is often high. Another feature is that the worse the regulation of pressure in the mains the more failures of lamps; thus the consumers have to pay for the misdeeds of the suppliers of electricity.

A system of free supply of incandescent lamps has been proposed by Mr. A. H. GIBBINGS, and is now in operation in Bradford.

The basis on which the supply is given is the following:—16 candle-power lamp burning 1,000 hours consumes 60 units; 25 candle-power lamp burning 1,000 hours consumes 94 units; 32 candle-power lamp burning 1,000 hours consumes 120 units; 50 candle-power lamp burning 1,000 hours consumes 188 units, and so on. Every good lamp is supposed to last 1,000 hours burning.

Every consumer is entitled to one 8 or 16 candle-power lamp for every 60 units consumed; and if higher candle-power lamps are required instead of 16 candle-power, the number of lamps to which the consumer is entitled will be in inverse ratio to the candle-powers. This is in brief the system, but there are many other details which are not of sufficient general interest to go into here.

The object of the system is to encourage the consumer. It will certainly encourage a consumer who does not reason the system out—and they are perhaps the majority. To a business man, however, the gift of anything excites suspicion. Let us examine the facts in this case. A consumer is given a 16 candle-power lamp for every 60 units consumed; why not give him the value of such lamp as a rebate on his current, and let him buy his lamp, if he wants it? The answer is not evident, and is rather difficult to give. There is no guarantee of the lamp, so the consumer is not relieved from the annoyance of premature failure, although the lamp is "carefully tested." All lamps should be carefully tested before leaving the maker, but this will not prevent bad lamps getting used; in fact, if the illustration be permitted, you cannot tell the qualities of a lamp before it is broken (in use) any more accurately than you can those of an egg. The expense of this free lamp is charged to the electricity department, and so the consumers of course really pay for it, although indirectly.

A guarantee system proposed by the writer for certain towns is as follows:—

The consumer may, if he likes, pay for one lamp per holder per annum; all lamps required over and above that

are supplied free, if the lamps blacken badly or are broken owing to being defective. If there is any doubt about a lamp being bad it will be tested, and if the candle-power is 30 per cent. less than the declared, or the energy consumed per candle-power have increased 30 per cent., it will be taken as defective. A few precautions which will be taken to prevent fraud, &c., are as follows:—All old lamps must be returned, and they will all be marked distinctively before being sent out (probably numbered). To avoid too much testing a charge of 6d. will be made for each lamp tested if it proves to be up to the standard mentioned.

The object of this system is that the consumer who is a long-hour consumer, and who will use more than one lamp per holder per annum, will get a rebate by this means; the system will guarantee the life of lamps, and so avoid the dissatisfaction which often occurs over this point; it will encourage the purchase of good lamps from the supply company (to whose interest it will obviously be to supply the best), and it will penalise the company if they keep an unsteady pressure on the mains. It is a business arrangement which will, by the law of averages, very nearly, if not quite, pay for itself, and which will tend to give the consumers confidence in electric lighting.

A defect in the Bradford system is that undue preference is given to incandescent lighting, and it is asked, "Why not give free carbons for arc lamps and brushes for motors?" This objection has, no doubt, great weight in the case of the Bradford system. Mr. GIBBINGS should give one pair of carbons for each 8 hours burning of the arc lamp, also a pair of brushes for each 1,000 hours running of the motor, to be consistent. In the case of the latter system mentioned (the "guarantee" system), this might be done in a similar way to that of incandescent lamps, and would be done if desired. If a consumer pays for a pair of brushes per annum, and the company has supplied or approves of the motor, he will be supplied with all the brushes he needs, and if the consumer pays for carbons for 1,000 hours burning, the company will supply him with all the carbons he needs, and see that they are good.

From this and previous articles it will be seen that there is no lack of enterprise on the part of suppliers of electricity, and it only needs a very few more years and there is no doubt that electricity will be as much used as gas; the long-hour and best consumers will find it cheaper than gas, while the gas companies will be left with the short-hour consumers, whom they can supply cheaper than can the electricity supply authorities. With free wiring, prepayment meters and free lamps, and large rebates to long-hour consumers, electricity will be the light of the "masses" as well as the "classes."

THE AUGUSTINE CELEBRATION.

THE following is the programme to be observed at the visit of the Anglican bishops to Ebbs Fleet and Richborough on (to-day) July 2:—The special train for the bishops and Church dignitaries will leave Charing Cross station at 1.35 P.M. It will reach Canterbury at 3.10 p.m., and will there be joined by the Dean and Chapter of Canterbury, the cathedral choir, and a few others to whom tickets have been allotted. The train will arrive at Ebbs Fleet at 3.35 P.M., and a commemorative service (drawn up by Archbishop Benson) will be held at St. Augustine's Cross. The enclosure at Ebbs Fleet will be reserved for those who travel by the special train, but the public generally will be admitted to the adjoining field on payment of a small fee to the tenant. The train will leave for Richborough Castle at 4.25 P.M., and a procession will be formed at 4.45 P.M., consisting of the bishops and the mayor and corporation of Sandwich, from the north postern gate to St. Augustine's Cross, in the centre of the castle grounds. There Psalm xcvi. will be said, and a brief address will be given by Canon Routledge on the history of the castle. Tea will afterwards be provided by the trustees for bishops and other invited guests. The public will be admitted at the west gate on payment of 1s. to the custodian. The special train will leave Richborough at 6 o'clock and is due at Canterbury at 6.30.

On returning to Canterbury the bishops will receive the hospitality of the residents, each bishop having been invited to become the guest of a citizen. It is arranged that at ten minutes to ten on Saturday, July 3, the archbishops and bishops (not wearing their robes) will meet at the lych-gate of the historic church of St. Martin, where they will be received by the choir and clergy. The hymn "The Church's one founda-

tion" is to be sung as the procession goes to the church, where a form of service, lasting about a quarter of an hour, will be gone through. The special Litany of St. Augustine, which the monks sang on entering Canterbury, will be rendered to music specially composed for the occasion by the Rev. F. H. Hichens, hon. canon of Canterbury Cathedral. Special prayers in connection with Queen Bertha, King Ethelbert, St. Augustine and St. Martin are also to be offered, and the service will conclude with the hymn "We love the place, O God." Having inspected the church, the bishops will have time to walk from the Quenen Lane and Bowling Green to the cathedral. The special service, at which the archbishops and bishops will be addressed in the cathedral by the Archbishop of Canterbury from the steps of the chair of St. Augustine, will take place on Saturday, July 3, at 11.30. The Kentish mayors, military officers and others will assemble at the Guildhall and will walk in procession. Others will assemble at the Guildhall and will walk in procession to the cathedral by 11.15. The bishops will robe in the crypt and will pass in procession through the cloisters to the west door of the cathedral, where they will be received by the Archbishop of Canterbury, Dean Farrar, the cathedral clergy, the rural deans, the city clergy and others. The bishops will be seated on the sacarium and choir steps, the Archbishop of Canterbury occupying the patriarchal chair of St. Augustine, which will be placed in front of the communion table. An allocution by the archbishop will follow the singing of the Te Deum, and Handel's Hallelujah Chorus is to be rendered at the close prior to the Benediction. After the service the mayors of the chief towns will be presented to the Archbishop of Canterbury outside the west door of the cathedral. The representatives from other boroughs are subsequently to be entertained by the mayor of Canterbury. After the service all the archbishops and bishops are invited to a public luncheon at St. Augustine's College at 1.30. After the luncheon there will be time for any of the bishops who desire it to visit the cathedral or the ruins of the ancient church of St. Pancras, dedicated by St. Augustine and close by St. Augustine's College. Evensong will be at 3.30. After the evening service at 4.30 all the archbishops and bishops are invited to a reception at the deanery. The Archbishop of Armagh will preach at the cathedral on July 4 at the service commencing at 10.30. In the afternoon at 4 P.M. it is proposed that a sermon shall be preached in the nave of the cathedral by the Bishop of Christchurch to men only. In the evening at 6.30 the preacher will be the Bishop of Ripon. Trains will be arranged to be run on Monday morning, July 5, from Canterbury to Victoria and Charing Cross, arriving in ample time for the Lambeth conference. On Sunday, July 11, the sermons at the cathedral will be preached at 10.30 by the Bishop of London, at 3 by one of the colonial bishops, and at 6.30 by the Bishop of Newcastle.

EASEMENT OF SUPPORT.

JUDGMENT has been given by Mr. Justice Bruce in the important case *Greenwell and Others v. the Low Beechburn Coal Company*, which was tried at the last Durham assizes. The decision will affect other cases in which the easement of support is introduced. The plaintiffs' houses were injured by subsidences, which it was alleged were caused by the defendants' removal of the supports in the coal mines. Having described the circumstances, Mr. Justice Bruce said:—

The general question of the liability of the owner of mines for injury caused by reason of his underground workings to the surface and to buildings upon it has been much discussed in recent years. In *Bonomi v. Backhouse* the question raised was whether the statute of limitations ran from the time of the accruing of the damage or from the time of the taking away of the support which caused the damage. It was finally decided by the House of Lords that the statute did not begin to run until the time of the actual happening of the damage. In order to determine the question when the statute began to run it became necessary for the judges to consider the nature of the right which gave rise to the cause of action. Here it is necessary to observe that although the right of the owner of the surface and the right of the owner of the buildings on the surface not to have the land or buildings interfered with by underground working on the part of the owner of the minerals stand upon different footings as to the mode of acquiring them, yet the right as regards buildings when once acquired is in character the same as the right of the owner of the surface. As I have already observed, the buildings in question in the present case at all material times were more than twenty years old, and were in the nature of ancient buildings, and it will be necessary, in discussing the character of the right, to distinguish between land and buildings. For practical purposes in this case the character of the right in each case is the same. Wightman, J., in giving his judgment in *Backhouse v. Bonomi*, expresses the opinion that the cause of action was founded upon a breach of duty on the part of the defendant by so using his property as to injure that of his neighbour and not upon any

right of the plaintiffs to an easement in, upon or over the land of their neighbours. In the Exchequer Chamber, Willes, J., in delivering the judgment of the Court affirming the view expressed by Wightman, J., says, p. 659:—"We think that no cause of action accrued from the mere excavation by the defendant in his own land so long as it caused no damage to the plaintiff, and that the cause of action did accrue when the actual damage first accrued." In the same case in the House of Lords, Lord Cranworth says:—"It has been supposed that the right of the party where land is interfered with is a right to what is called the pillars or the support. In truth, his right is a right to the ordinary enjoyment of his land, and until that enjoyment is interfered with he has nothing of which to complain." In *Lamb v. Walker*, Lord Chief Justice Cockburn, referring to the decisions of the Exchequer Chamber and the House of Lords in *Blackburn v. Bonomi*, says:—"The decisions establish conclusively and incontrovertibly that it is not the withdrawal of the support previously afforded by the adjacent strata—a support to which, according to the view there taken, the adjoining owner had abstractedly no right—but the actual disturbance of his enjoyment of his property which constitutes a wrong and gives a legal ground of complaint. . . . The act of the excavating owner is not tortious *in se*; it is tortious only when it produces, and, as it seems to me, to follow logically to the extent to which it produces actual damage." The same view of the nature of the right of action in cases of this character is expressed by the judges in the Court of Appeal in *Mitchell v. Darley Main Colliery Company*, and in the same case by the majority of the judges in the House of Lords. In the last-mentioned case the defendants in 1867 and 1868 worked a seam of coal lying under and near to the plaintiff's land. A subsidence took place in 1868 and continued until 1871, and cottages of the plaintiff's were damaged by the subsidence. The plaintiff made a claim upon the defendants in respect of that damage, and the defendants repaired the damage, and so satisfied and discharged the cause of action in respect of that damage. Afterwards, without any further working on the part of the defendants, a further subsidence took place in 1882, caused wholly or in part by the defendants' workings in 1867 and 1868, and did further damage to cottages of the plaintiff's. On September 27, 1882, the plaintiff brought an action for this further damage. The defendants pleaded the Statute of Limitations, but it was held in the Court of Appeal and in the House of Lords that the plaintiff was entitled to recover. The judgments of the Master of the Rolls and the other judges of the Court of Appeal in *Mitchell v. Darley Main* affirm the principles laid down in the earlier cases to which I have referred. But there are some expressions in the judgment of the Master of the Rolls which the defendants in the present case have relied upon as supporting their contention. At page 129 the Master of the Rolls says:—"What they (the defendants) did in excavating was perfectly lawful, if they had taken care that in so using their property they did not hurt him (the plaintiff); but in 1868 or immediately afterwards they did something which did give him a cause of action—that is, they caused his land to subside. . . . That cause of action was settled between them when they repaired his houses, but now they have done him a new and wholly independent injury, they have caused his land to subside again. . . . They have caused that subsidence by the excavation of the minerals in 1868 and by not having filled up the excavation before 1882. I cannot help thinking that the judgment of the Lord Chief Justice . . . examines the whole subject afresh, and gives the most weighty reasons to show that in such a case as this the only cause of action is the subsidence of the plaintiff's land, and if that subsidence has been brought about by the defendants, whether or not by the omission of something after commission—that is, without taking precautions against the consequences of an act of commission by them—each subsidence is a new cause of action, although the *causa causans* of each subsidence may be the same. It may be argued that the *causa causans* is not the same. The *causa causans* of the first is the excavation; the *causa causans* of the second is, as a matter of fact, the excavation unremedied, or the combination of the excavation and of its remaining unremedied." It is contended that some of the phrases in the judgment I have quoted support the view that the *causa causans* of the second subsidence in *Mitchell v. Darley Main* was the neglect to fill up the excavation. But I think that the judgment must be read in connection with the facts of the case, and the Master of the Rolls nowhere speaks of the simple neglect to fill up the excavation or to provide artificial support as an act of omission of such a character as to give a cause of action. In each case he speaks of the taking away of the support and the neglect to provide artificial support as acts which, taken together, operated to cause the subsidence so as to give a right of action. But even if the words can be so construed as to lead to the conclusion that the neglect to provide artificial support of such a character as to prevent the second subsidence was to be regarded as the cause of action, it does not follow, because there is an obligation upon a person who has made an excavation of such

character as will, if left without being artificially filled up, cause successive subsidences in his neighbour's land, to prevent the subsidence by providing artificial support, that therefore a similar obligation attaches to a person who is merely in possession of the minerals, and has done no act calculated to cause damage to his neighbour. I do not think any of the expressions in the judgment I have referred to support the contention that where a subsidence causing damage to the surface arises from excavations in mines a person who has not been concerned in making the excavation, and who happens to be in the possession of the mines before and at the time of the subsidence, is liable for the damage caused by the subsidence simply because he did not take measures to arrest the subsidence. It remains to consider the judgment of Lord Blackburn in the same case delivered in the House of Lords. Lord Blackburn dissented from the judgment of the other judges in the House of Lords, and it is contended that the reasons he gives for his dissent strongly support the contention of the plaintiffs in the present case. He refers to an expression used by Lord Justice Bowen in his judgment in the same case in the Court of Appeal. The Lord Justice had referred to *Whitehouse v. Fellowes*. In that case the trustees of a turnpike road had constructed a covered drain with catch pits to carry off the water from the surface of the road into the drain; but, in consequence, as the jury found, of the negligent way in which the catch pits were constructed and kept, the drain was insufficient to carry off the water, and it was diverted to the plaintiff's land and drowned his colliery. A statute limited the period for bringing an action against the trustees to within three months after the fact committed. The action was brought within three months of the particular damage complained of, but more than three months after construction of the drain and catch pits. It was held that, as an injury was done to the plaintiff by reason of the improper management of the catch pits, he was not bound to rest his complaint upon the original construction of the works, but that the continuance by the defendants of that negligent and improper condition of the road under their charge, if accompanied by great damage to the plaintiff, constituted a fresh cause of action. Lord Justice Bowen, in *Mitchell v. Darley Main*, says:—"Applying the reasoning of *Whitehouse v. Fellowes*, it seems to me that there has been not merely an original excavation or act done, but a continual withdrawal of support—that is to say, not merely an original act the results of which remain, but a state of things continued, and a state of things continued which has led to and caused the subsequent damage." Lord Blackburn, referring to that passage, says:—"If I could take that view of the facts I should agree in the conclusion. But I cannot take that view of the facts." It seems to be clear why he could not take that view of the facts. During the argument of the case in the House of Lords a statement was agreed to in writing between the appellants' and respondents' counsel, and part of that statement was as follows:—"That after the partial subsidence in 1868 the strata remained practically quiescent until the working of the coal in the next adjoining land in 1881." After that statement had been agreed upon, it was, I think, impossible to treat the case as if the facts proved had shown that there had been a continual withdrawal of support. Then Lord Blackburn proceeds to point out what in his opinion would be the consequence of assuming that in all cases of successive subsidences there had been a continual withdrawal of support. Lord Blackburn is not, I think, to be understood as saying that any such consequences follow from the judgment of the House. He did not agree with the law as laid down in that judgment. He did agree with the conclusion of law laid down by Lord Justice Bowen in the passage he referred to, but he could not agree in the view of the facts upon which the conclusion was founded. And he points out what would be, in his opinion, the consequence of holding the defendants liable upon the assumption of fact that there had been a continued withdrawal of support. When the passage of Lord Blackburn's judgment is carefully examined, it seems to me that it does not afford support to the contention that such consequences as he mentions follow from holding the Darley Main Colliery Company liable upon the grounds upon which the House of Lords held them liable. It remains to consider whether, on the general principles of law, the defendants can be rendered liable upon the ground that they have allowed a nuisance to continue on their land which has caused damage to the defendants. It is upon this principle that the learned writer of a valuable text-book on the Law of Support contends that the person in possession of the mines at the time when the subsidence took place may be rendered liable for the damage caused by the subsidence. ("Banks on Support," pp. 5-7.) There is a dictum of Mr. Justice Littledale in the case of *Laugher v. Pointer*, which is frequently quoted. That very learned judge, in the course of his judgment, says:—"And the rule of law may be that in all cases where a man is in possession of fixed property he must take care that his property is so used and managed that other persons are not injured, and that whether his property be managed by his own immediate ser-

vants or by contractors or their servants. The injuries done upon land or buildings are in the nature of nuisances, for which the occupier ought to be chargeable when occasioned by any acts of persons whom he brings upon the premises." The question before the Court in *Laugher v. Pointer* was whether the defendant could be rendered liable for the negligent driving of a driver who had been provided by a livery stable-keeper. No question arose as to the character of the act; the only question was whether the defendant could be rendered liable for the acts of a man who was not his servant, and it was with respect to that question that Mr. Justice Little-dale was referring in the passage in question. He was explaining that in some cases, where acts in the nature of wrongful acts had been committed by persons not the servants of the occupier, the occupier had yet been held liable on the ground that he is in law answerable for the acts of persons whom he brings upon the premises. It seems to me that the true rule is laid down by Baron Rolfe in *Reedie v. London and Great Northern Railway Company*. He says:—"It is not necessary to decide whether in any case the owner of real property, such as land or houses, may be responsible for nuisances occasioned by the mode in which his property is used by others not standing in the relation of servants to him or part of his family. It may be that, in some cases, he is so responsible. But then his liability must be founded on the principle that he has not taken due care to prevent the doing of acts which it was his duty to prevent, whether done by his servants or others." This leads me to consider the question, What act has been done which it was the duty of the defendant to take due care to prevent? The answer must be that he has not taken due care to prevent the subsidence. But what duty was there on his part to prevent the subsidence? He had taken no part in the excavation. The excavation was not wrongful. Until the damage ensued there was no cause of action, no cause of complaint against anyone. How, then, did the duty arise by which it became incumbent on the defendant before the subsidence took place to anticipate or prevent the subsidence? It is said that the defendant was bound so to use his land as not to injure his neighbour. So he was. But he has done nothing to cause injury to his neighbour; and unless he is under an obligation to prevent the consequences of an act done by his predecessor in title, he has not been guilty of any omission of duty for which he can be rendered liable. It is suggested that the excavated strata left without any support was a nuisance; but I do not think it was. Until the actual subsidence happened there was nothing unlawful in the state in which the land was left. At no moment prior to the subsidence can it be said that there was any duty upon anyone to provide artificial support, and therefore it seems to me that it cannot be said that the defendants are guilty of a default of duty in allowing a state of things to continue which was a perfectly lawful state of things. It was contended that the principle laid down in *Fletcher v. Rylands* applies. The principle decided in that case is thus shortly stated by Mr. Justice Blackburn in the Court of Exchequer Chamber, and the passage is cited with approval by the Lord Chancellor in his judgment in the House of Lords:—"We think that the true rule of law is that the person who for his own purposes brings on his land and collects and keeps there anything likely to do mischief if it escapes must keep it at his peril; and if he does not do so is *primâ facie* liable for all the damage which is the natural consequence of its escape." The present case does not seem to me to fall within the rule. The defendants did not create a state of things likely to do mischief; they did nothing to continue or keep up the state of things likely to do mischief, and they did not invade the plaintiff's right of property by suffering any mischievous thing to escape from their property on to his. It seems to me that there is no analogy between the two cases. In the judgment of Lord Halsbury in *Mitchell v. Darley Main* the case of *Fletcher v. Rylands* is referred to, not as affording an illustration of the principle upon which the right of action in *Mitchell v. Darley Main* rested, but as affording an example of a state of facts in which successive causes of damage would give rise to successive actions. It follows, from what I have said, that I cannot discover any grounds upon which the defendants can be held liable in law to take active steps to prevent the damage to the plaintiff's land resulting from an excavation which they did nothing to make or to continue. But I may observe that if in any case any such obligation were imposed upon them such obligation could only arise in cases where it is proved to be practicable for the defendants by artificial support to have prevented the subsidence. In the present case there is nothing to show that that would have been possible. I was not asked to leave any question to the jury on that point, but I think there is little doubt that if the question had been asked they would have found that it was not possible for the subsidence to have been prevented by any act of the defendants, unless, indeed, they had taken such steps immediately upon their entering upon their lease. The workings which occasioned the mischief were carried on by Sharp not later than 1889; the subsidence complained of took place after May 30,

1893. Although it may be possible in some cases soon after minerals have been worked out to prevent subsidence by providing artificial support, yet when a considerable period has been allowed to elapse after the workings have been carried on the roof of the workings falls in, and it is generally exceedingly difficult, if not impossible, to arrest the subsidence, which commonly begins in the lower strata some time before it reaches the surface. But I do not think it is necessary to speculate concerning this matter, because there is certainly nothing to show that the defendants could by any means have prevented the subsidence. In the result I enter verdict and judgment for the plaintiff for 50*l.* for the claim in respect of fields 197 and 201 and costs. On the other issues I find for the defendants.

SUSSEX ARCHÆOLOGICAL SOCIETY.

AFTER a term of service extending over rather more than ten years, Mr. John Sawyer has resigned his appointment as clerk to the Sussex Archæological Society, closing his official connection with the Society amid very cordial expressions on the part of the committee as to the manner in which his duties have been performed. The severance has been brought about in consequence of many of the duties hitherto falling to Mr. Sawyer's share having, owing to recent changes, passed into the hands of honorary workers, the services of a clerk, except for mere routine work, being no longer required. Full of knowledge of Sussex history and local traditions, Mr. Sawyer has during the past eight or ten years been the means of adding very materially to the interest in the Society by his careful attention to its publications and his attractively written guides to the places visited on the occasions of the annual excursions. In other ways familiar to members he has devoted himself to the Society, and it is hardly probable that he will be permitted to retire without recognition from his many friends among the members all over the county.

THE ARCHITECTURAL ASSOCIATION OF IRELAND.

THE annual excursion took place on Saturday, June 12. The party, numbering about twenty-five, assembled at Amiens Street in time for the 9 A.M. train to Drogheda. On the arrival of the train at Drogheda brakes were in readiness to convey the party to Mellifont; the drive thither was through an exceedingly pleasant country, the route taken being along the valley of the Boyne, passing by the scene of the historic fight where the last of the Stuart kings made his final effort to retain the crown. An obelisk to commemorate the victory of King William marks the spot. Close to this the road crosses the river into the county Louth by an iron lattice-work bridge. A little further on the way was through the beautiful demesne of Mr. R. H. Balfour, D.L., Townley Hall.

On arrival at Mellifont Abbey the party visited the remains of this fine Cistercian abbey. Of the church itself little remains but what suffices to mark the lines of the plan, which is of the usual Cistercian type; but the octagonal baptistery is a building unique in its character in Ireland portions of it are in good preservation, the mouldings of its richly-proportioned arcade of round arches being frequently wonderfully sharp. The detail is of a transitional type. The chapter-house is in much better condition, and, strange to say, still boasts its vaulted ceiling—not a common thing in Ireland. The detail is of Early Decorated character and is very good. A small handbook has recently been issued containing some illustrations by Mr. Scott, of Drogheda (a member of the Association), which gives an excellent account of the remains of the abbey. A striking thing is that beyond the plan of the church there is little or nothing left of that type of architecture generally associated in one's mind with a Cistercian foundation.

After luncheon the party drove on to Monasterboice, where the two admired examples of Celtic crosses were examined with much interest; there are also a few small and quaint tombstones of the last century. Some of the party ventured on the long climb to the top of the round tower, from which there is a wide view. Several photographic groups having been taken by Mr. Hudman and Mr. Coleman both here and at Mellifont, the party started back for Drogheda, which was reached sufficiently early to give time for a stroll round the historic town. Amongst the places viewed were the old city wall and St. Lawrence Gate, the constabulary barracks (an old and rather quaint Georgian building), the new Roman Catholic Church of St. Peter, the abbey, &c.

The members dined together at the White Horse Hotel.

The New Booking Hall at Waverley Station, Edinburgh was opened to the public on June 28.

NOTES AND COMMENTS.

THE old Ecole de Médecine of Paris, which is supplanted by M. GINAIN's building on the Boulevard Saint Germain, occupies three sides of a paved court, and covers a large area of ground. It now belongs to the city of Paris, and is to be converted into an historic museum of medicine and library of medical works. The building stands on the site of the old College de Bourgogne, and the first stone was laid in 1769. The Faculty of Medicine was constituted as a corporation towards the end of the thirteenth century, but until 1427 it did not possess a school. The licentiates and regents who formed the body of "scholares" used to meet in the parvis of Notre-Dame. The body-physician of CHARLES VII. subscribed 300 golden crowns towards building a school in the Rue de la Bûcherie. The hall, which used to hold 1,400 auditors, was used of late as a laundry, and the chemicals employed have acted injuriously on the architectural works. In the course of the restoration the discovery was made of a vaulted crypt, which is supposed to date from the thirteenth century, and formed part of the "Maison de Bedeaux."

AMONG the countless articles by foreigners on the event of last week, there is not one more deserving of consideration than the "Réflexions d'un témoin sur le Jubilé" by M. PAUL BOURGET, who is the favourite literary psychologist of the Parisian monde. He was invited by the trustees of the Taylor Institution, Oxford, to lecture on GUSTAVE FLAUBERT, the author of "Salammbô," and from his official position, although it was not to be held for a long time, he was eager to understand the people he had undertaken to instruct. To M. BOURGET the peculiarities of the English character were as apparent among the cottages around Oxford as in Piccadilly, Pall Mall, the Strand and Cheap-side. We are to him the only people who know how to conserve antiquity without any sacrifice of modern needs. In Oxford he found all the old buildings preserved without the sacrifice of one stone and all the Mediæval foundations. But at the same time it is not considered incongruous to make a MAX MÜLLER a fellow of All Souls College, an institution that was founded in order that there might be always priests to pray for the souls of the soldiers who fell at Agincourt. France, he says, has suffered because NAPOLEON taught the people to ignore the power of the past. He compares him to one of the monastic painters of the Renaissance, who filled long lengths of cloisters with their own works regardless of the primitive works which had to be sacrificed. And hence it is that for the past century France, when in difficulties, has sought for a new man with creative power, who was ready to sweep away whatever existed and to substitute new creations. It seemed to M. BOURGET to be no less strange how the claims of the present were never ignored amidst the enthusiasm. The announcement that business was carried on as usual expressed to him the spirit of the race. Nothing should be lost, neither time, nor trouble, nor money. The crowds in the streets had a definite idea of what they were to see, and consequently they went along their ways without any of the exclamations which are to be heard during festivity in Paris. But, says M. BOURGET, a London street is merely intended as a place to pass over; it is a sort of tool which is employed in business, and not an open club where one can remain and wax eloquent as in Paris. Never was its utilitarianism made more manifest than during the Jubilee week. M. BOURGET does not wish to see Paris transformed into an imitation of London, but he desires his countrymen to act like a true artist before the *chef-d'œuvre* of a rival. In other words, to endeavour to comprehend English ways instead of envying them or deriding them.

THE Compensation for Accidents to Workmen Bill which is now before the House of Commons has been carefully considered by the Faculty of Advocates of Scotland. According to the report a majority of the committee have approved of the principle of the proposed legislation. It was not proposed in the Bill that the new liability should be imposed upon employers in all trades. Certain trades in which it was proposed to impose it were mentioned in the fifth section of the Bill. The result would be, that from the mere nature of their employment some workmen

would have a claim to compensation for accident and others would not. A majority of the committee were of opinion that as the Bill was essentially of the nature of an experiment, and that as the trades selected and enumerated were those to which, if any, the new proposals might be tentatively applied, it would be undesirable, in the interests both of employers and workmen, to extend the new legislation to other trades till experience of its working was obtained. The committee also suggested certain alterations in the sections and schedules. A minority of the committee differed from the principle of the measure. They thought that the employer ought to be liable for any accident for which he could be proved to be in fault. But they objected to his being made to insure the servant against accidents whether arising from fault or not. A system of insurance to which both parties contributed had much to recommend it. But that was not the system of that Bill. Prior to the Bartonshill case in 1858, it was generally understood in Scotland that the employer was liable to his servant for the fault of another servant, just as he is to a stranger. The employer chose all his servants and supervised all. There might have been no injustice in making him liable for all. The abolition of the doctrine of common employment would have been a serious change in the law. But in placing a burden upon capital it would have come far short of what this Bill proposed. It was agreed to send copies of the report to the members in charge of the Bill and to Scottish members of Parliament.

THE French manufacturers appear to have discovered a market in Spezzia for tiles for floors, kitchens, dadoes, &c. These tiles are square, hexagonal and octagonal in shape, measure 10 by 10, 15 by 15, 20 by 20 centims., &c., are thin and light, but strong and on the whole well finished; the smaller sizes are of plain red cherry and dark colours, but the larger ones are of various coloured part designs (several tiles being required to make up a complete design). The importers generally undertake to lay them from 4 fr. 50 c. per square metre. The importation of these French tiles in 1896 showed an increase, notwithstanding the considerable arrivals of Italian-made tiles of good quality and similar dimensions. The total importation by sea and by rail was 2,965,264 thousands.

THE Arundel Society was to some extent an exponent of Ruskinism. By the elaborate coloured lithographs issued from the Society people who could not find time to visit out-of-the-way churches in Italy were enabled to realise the characteristics of many of the early painters. As there is now less admiration for that variety of art the subscribers were gradually reduced until at present the income does not meet the expenditure. Photographic illustrations were found to be more truthful than the lithographs, which, being produced in Germany, latterly gave occasion to much prejudice against them. The collection of water-colour drawings prepared for the lithographers is valuable and will no doubt be offered to some public gallery. But the admiration for GIOTTO, FRA ANGELICO, ORCAGNA and others is waning, although it may one day be revived.

WHEN the number of sculptors and students in England who can produce busts is considered, it would have been satisfactory to learn that all those of the QUEEN which are required during the present year were produced in Great Britain. Many of the commissions, it appears, have been secured by artists in Spezzia. Orders for Great Britain and the Colonies are generally received through British firms at Carrara. It is no wonder the prospects of the marble-workers are brighter than usual, and that full employment is to be obtained by sculptors. The output in 1896 exceeded that in 1895 by nearly 6,000 tons, the figures for the two years being 141,811 tons in 1895 and 147,609 tons in 1896. Block, ordinary and statuary marble amounted to 91,916 tons and sawn marble to 55,693 tons. The monthly output varies from 10,000 to 14,000 tons. There has been also an increased exportation to the United States, the Carrara merchants being anxious to push forward their shipments thereto before the new MCKINLEY tariff (which imposes a higher duty on Carrara marble) came into operation.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ON Monday a meeting of the Institute was held for the purpose of the presentation of the Royal Gold Medal to Dr. Cuypers. The president, Professor Aitchison, A.R.A., delivered the following address:—

The last Monday in June is always a day when the members of the Institute feel proud and happy, happy because our meeting is graced by the presence of ladies, of distinguished visitors and of old friends; and proud because it is the occasion when Her Majesty the Queen is gracious enough to show her interest in architecture by giving her Gold Medal to a distinguished architect or writer. There is additional exhilaration this evening on account of Her Majesty's Diamond Jubilee, when the whole empire has rejoiced, and been thankful for the increase of liberty, knowledge, peace and plenty under her fostering care, and for the example of the virtues she has shown; but also because the medal is to be bestowed on a foreign architect, for this shows the breadth of Her Majesty's views and largeness of her sympathies. Our great art, that Aristotle calls one of the master arts of the world, rules over a wide domain, for wherever man has cultivated his intellect and faculties and raised his contemplation to a supreme being, sublime temples have been raised. In contemplating the glorious and captivating domain of art we are taken out of ourselves, and not only feel the ennobling flame that the fine arts kindle within us, but are forcibly reminded of the brotherhood of man. More than half of our solaces and delights are due to the great creators and discoverers who lived in remote ages and in countries it has perhaps never been our good fortune to visit, though we now have the glories of architecture brought home to us through the arts of drawing, engraving and photography.

However we may be delighted with the works of nature, which she has sculptured and painted for our solace and instruction, however greatly we may be moved by the sublimity of her mountains or awed by the resistless force of her waters, there is a charm about architecture that touches us more closely, for in its works we see forms of beauty designed by man for man's delight; while the colossal structures that man has created, though insignificant as compared with nature's works, still astonish us, for they recall to our minds that they have been the works of countless pigmies like ourselves, raised to excite emotions that still tell of the builders' gratitude to superior powers. Even the pyramids raised to the rulers of Egypt, whose outlines break the long line of the desert, show rather thankfulness for the honour once bestowed on their occupants than the pride of kings. The charms of certain masterpieces of architecture are not to be effaced from the memory, and vie with the recollection of nature's beauties, if they do not surpass them. I may mention the matchless perfection of the temples that crown the Acropolis of Athens, the hoary majesty of Nerva's forum, the sublimity of the interior of the Pantheon, the vastness, richness and striking forms of Santa Sophia and of that jewelled casket St. Mark's, as well as the more refined features of the Palazzi Vendramin, Manzoni and Cornaro-Spinelli, the Scuola de San Marco and the churches of Santa Maria della Salute at Venice and Santa Maria dei Miracoli at Brescia, while the wonders of the cloud-piercing fronts and spires of the Mediæval churches are equally ineffaceable.

Architecture not only throws a lustre on the reigns of kings, but in the monuments it erects sums up more completely than any other art the cultivation and tendencies of the nation, keeps its memory green, and when its glory has departed and all else has been swept away, still points to the greatness and intelligence of its people.

I have now to introduce to you the distinguished Dutch architect, Dr. Cuypers, on whom you are about to bestow the Gold Medal. It is usual to give a slight sketch of the life and works of the Gold Medallist in the interest of those who cannot be here, and many of those who would be here to-night are in the uttermost parts of the earth. So I must ask Dr. Cuypers to bear with me a little longer.

I can hardly think of Holland as a foreign country, so intimate has been the relation between it and England,—for did not Holland give us one of our revered kings, William of Orange, and many of our celebrated families?—and so warm is

still our sympathy with its soul-stirring efforts in the cause of freedom. Most of us when at school translated Grotius and the dialogues of Erasmus, that friend of Sir Thomas More whom he called "his darling." Who does not love the Dutch school of painting and feel at home with its creations? Who has not been enchanted by the power of Rembrandt and the vigour of Frank Hals, with the crystal purity of the colour of Peter de Hooze, with the woods of Hobbema, the rushing waters of Ruysdael and the beautiful architectural works of Van der Heyden? Who has not been fascinated by the dignity of those warriors and statesmen, and by the grace and loveliness of those high-born ladies that live for us again in the pencil of Vandyke; who has not in imagination shared in the hardships and rejoicings of such discoverers as Van Diemen and Tasman?

Dr. Cuypers follows a long line of distinguished Dutch architects to whom we owe the admired Mediæval churches, town halls and mansions, as well as the wondrous cathedral of Antwerp, and, in Renaissance days, the Villa Borghese and the Portal of the Vatican, designed by Van Santen, under the name of Vasanzio, for Pope Paul V., when Floris, Philip Vingboons, Van Campen and Post enriched their native country with their works, and Henrick built our Royal Exchange for Sir Thomas Gresham, all of which have been presented to us in the publication of Mr. Ysendyck. It is not usual to give the age of our Gold Medallist, but on this occasion the arrival of Dr. Cuypers' seventieth birthday this year has been the cause of almost national rejoicings in Holland; this points to something in his personality and career that has touched the hearts of his compatriots in a way that no mere quantity or excellence of his works could insure.

Dr. Petrus Josephus Hubertus Cuypers was born on May 16, 1827, at Roermond. In his nineteenth year he became a student at the Antwerp Academy, and got the prize for excellence and the gold medal for architecture in 1849. He began his practical career by the restoration of the Minster of Our Lady in his native town, and built his first church 1853. In 1864 he was awarded a crown for the William I. Museum, and up to 1894 he had built a cathedral and sixty-one churches and chapels; he had restored fifty-seven ecclesiastical buildings, mostly cathedrals and churches, and built museums, railway stations, mansions, villas, private houses and monuments, besides his great work of the Royal Museum at Amsterdam, some 450 feet long and 280 feet deep, with a central hall 70 feet wide and 260 feet long, the whole building comprising two quadrangles 130 feet long and 100 feet wide; it is built of brick with stone window jambs, mullions and bands. The style adopted is Late Gothic, just feeling the first breath of the Renaissance when cusps had been abandoned. This, however, is by no means all we have to be thankful for, as he started schools all over Holland, where the innumerable handy craftsmen who carry out architecture were taught the elements of design belonging to their crafts.

His motto is, "I believe, I love, I hope," and he says, "The love which binds together my beliefs and my hopes makes up my life." In his own house he has inscribed an apothegm of architectural wisdom:—"Study the old, in order to win strength and support to design the new."

It is clear that any architect who had carried out such an enormous mass of work must have been guided by fixed principles systematically employed; and when no detail has been allowed to pass without his own supervision, and is mostly from his own hand, it is obvious that his industry must be equal to his genius.

Sir, you are said by your contemporaries to be the one man in Holland who has done more than any other to point the way to higher things, and to follow out his own teaching. I gather from the admiration that you excite in Holland that your character is as much revered and loved as your genius is admired, for without the existence of peculiarly admirable qualities we cannot believe that you would have so endeared yourself to your countrymen, for you have falsified the poet's saying that—

"He who surpasses or subdues mankind,
Must look down on the hate of those below."

I now beg in the name of the Royal Institute of British Architects to invest you with Her Majesty the Queen's Gold Medal and to enrol you amongst that company of gold medallists that sheds such lustre on our Institute and on our country, and to hope, both on behalf of the Institute and myself, that you may, like so many great architects, live long to enjoy the honours you have so well merited and the love that you have called forth and to add to the number of those works with which you have already so largely adorned your native land.

The medal was then presented, after which Dr. Cuypers replied in French, the following being a translation of his acknowledgment:—

Mr. President,—Allow me to express myself in another language than in your national tongue, which I deeply appreciate and revere, but would fear to profane by speaking imperfectly before this august assembly. My own Dutch

speech, although it partly has a common base with yours, in that old Saxon which, had it not been for Charlemagne, would have become the universal Germanic or Teutonic language, is familiar to only a minority of the inhabitants of Great Britain, and would not suffice to render me intelligible in this chamber. I have recourse to the French language, which has numerous relations with yours—witness the denominations of the provinces of Normandy and Brittany in France—and like English, but in a less degree, is heard in the most distant countries of the terrestrial globe, everywhere that civilisation and liberty have established their glorious reign.

I feel, Mr. President, that I must, before and above all, express to you my sincere thanks for the words, too kindly and too flattering, which you have been good enough to address to me.

If it is true that all approbation of our work flatters our pride, what satisfaction must we not feel when this approbation comes from those of our colleagues for whom we have reserved a place of honour in our esteem and our veneration?

Yes, at this hour I dare publicly and solemnly say that, if I have had any success in my career as an architect, the example which has been given me by my colleagues in Great Britain has greatly contributed to it.

When I visited England for the first time, so as to study the great monuments of our neighbours, it was not only the ancient and majestic cathedrals, the characteristic churches of little towns and villages, the splendid colleges and other monuments of bygone ages which delighted and deeply impressed me, but, above all things, the wise lessons which my honoured colleagues Pugin, Scott, Street, Burges, Clutton and so many others—only to speak of those who have gone before us into eternity—had drawn from the work of the great architects of the Middle Ages and of antiquity.

It was here that I saw applied, with that correct, rational taste which characterises your glorious nation, the pure, true and unchangeable principles of our art, which must be true, utilitarian and practical, and at the same time not offend against those elusive canons of beauty wherewith God has endowed us, to be the immutable appanage of those who cultivate the arts.

It was particularly in your country, my dear colleagues, that I learned to estimate at its just value the charm which proceeds from correct and persevering application of the difference between materials, as much with respect to their properties, nature and qualities as with respect to their colour and other æsthetic features. It was here that I learned to appreciate the great advantages that result from the survival of the old co-operative guilds of arts and crafts, by which you have been able to maintain for the execution of your works practical and capable craftsmen, worthy of the share in the work that is entrusted to them.

It was in your country more than anywhere else that I noted and admired the happy application of the good principles of the past to the needs of modern society, in all the works of your great masters.

If, on the one hand, your fair and interesting land attracted me with its rich monuments and its great analytical architecture, on the other the welcome given me by my dear colleagues, from my very first visit, was such that I was able to profit by all the advantages that friendship and urbanity can offer. If the old masters were there to instruct me and to stimulate my ambition by the contemplation and the study of the masterpieces of great periods, the living masters, their worthy rivals, gave me their aid in procuring me access to, and serving as my guides in all hidden nooks of interest, in all celebrated museums, in the innermost of all sanctuaries of art.

It was in 1866 that I had the honour of being elected honorary corresponding member of the Royal Institute of British Architects, a title which is held in high esteem abroad, and in itself gives a certain influence and position to any architect.

And who will be astonished if it is known that this noble Royal Institute is the great school in which has been and is still being formed all that England can produce of that which is glorious and illustrious in architecture?

The preservation and the restoration of the historic monuments of your ancestors, the imitation of ancient models, the assimilation therewith of new buildings, the formation of a legion of artists fighting, without ever losing ground, against those errors of every kind with which the depraved taste of certain periods threatened the sanctuary of art—these are the first-fruits of this glorious institution.

Another great service rendered by you to the whole artistic world is to be found in the important travels that you have undertaken so as to study the monuments of the most distant countries, without regard to the manifold sacrifices that such enterprises inevitably entail.

The remarkable publications in which are printed the results of these artistic peregrinations are and will remain a splendid memorial of your Royal Institute.

If on this day I have thought it behoved me to pay homage

to the Institute for the great services which it has rendered to the artistic world in general, I will beg you to believe me, my honoured colleagues, when I add that I feel doubly happy in being able to express to you my keen appreciation of the distinguished honour with which you have gratified me.

I venture to request the honourable President to be kind enough to act as interpreter for his foreign colleague before Her Majesty the Queen of England, in order to express to her my deep gratitude for the fact that she has deigned to confirm the choice of the Institute by honouring me with the Gold Medal in the Jubilee year—the very year when so many millions of faithful subjects are blessing Heaven for having given them as a sovereign the most accomplished woman who has ever worn a crown.

EXPLORATIONS IN BABYLONIA.

A CORRESPONDENT of the *Times* writes:—To have unearthed the ruins of the oldest city in the world, the foundations of which were laid some 6,000 or 7,000 years before the Christian era, is a reward of which an explorer might indeed be proud. Such good fortune seems to have fallen to the lot of Mr. Haynes, who for nearly five years has been in charge of the American expedition engaged in excavating the great mounds of Nuffar, in Northern Babylonia, the site of the ancient city of Nippur, the sacred city of Mullil or the "Older Bel" of the Semites.

The history of the expedition which since 1888 has worked upon this site is a remarkable one, and its great work has been so quietly done that it has attracted but little attention except among students of Assyriology. The work was undertaken by the University of Pennsylvania, the funds, which have amounted to about 70,000 dols., being provided by a small committee interested in the work. The expeditions of 1888-90 partook rather of a prospecting survey, and were under the direction of Dr. Peters. The trial trenches produced a harvest of about 10,000 tablets and inscribed objects, among them several records of Sargon I. and his son Naram-Sin, whose date, B.C. 3800, was by many regarded as the starting-point of Babylonian history. Troubles among the Arabs and the usual difficulties with the Porte delayed the work for three years. In 1893 the explorations were renewed under the charge of Mr. J. H. Haynes, and they have been carried on continuously ever since, and have produced results such as were never dreamt of even by the most ardent advocate of Babylonian explorations, and the history of civilisation has been carried back to an antiquity never thought of. The cause of this triumph is not far to look for. Hitherto, with the exception of the short expeditions of Dr. Budge and the late George Smith, the work of exploration has been entrusted to men who, able as they were as directors of the excavations, were in no sense of the words either archaeologists or Orientalists. The labours of Layard and Rassam obtained the magnificent collections of the British Museum, but they contributed little to our knowledge of the archaeology of the cities they explored. The methods of systematic research such as were employed by Curtius, Schliemann and Petrie, working on strictly scientific principles, laying bare stratum after stratum of the ruined city, noting with care the position of every object, no matter how minute, and above all the aid of photography, had never been applied until now, and the result is a complete revolution in our knowledge. By this method the history of the excavated city may be read like a book, each stratum as it is uncovered furnishing us with a chapter of its long-lost history. The story of Nippur, as read in its ruins, is indeed a remarkable one.

The great mounds of Nuffar are situated on the east bank of the now dry Shat-en-Nil, a great main artery navigation canal which once connected Babylon with the Persian Gulf. The central feature of the ruins is a vast conical mound, called by the Arabs Bint el Amir, "the Amir's daughter," which rises to a height of nearly 29 metres* above the surrounding plain. This mound marks the site of the great ziggurat or temple stage tower first built by Ur-Gur or Ur-Bahu, as he was formerly called, about 2800 B.C., and subsequently repaired and added to by later kings. This vast structure was the central point of the explorations by Mr. Haynes.

We have long been familiar with another of the great stage towers erected by Ur-Gur at Mugayyar, the ancient Ur; but the one at Nippur is the first that has been thoroughly explored. The tower rests on a basis 59 metres by 39 metres, and is built, like most of these Babylonian towers, with the angles to the cardinal points. It appears to have consisted, like that of Ur, of three stages only, not seven, like the later towers at Babylon and Khorsabad. Each stage had a thick coating of plaster, composed of clay mixed with chopped straw, and to protect the lower stage from the winter rain it was faced with kiln-burnt

* In this article the metric system is used, as by Mr. Haynes and Dr. Hilprecht in their reports.

bricks and a coating of bitumen. The ascent was on the south-east side, and here it would seem Mr. Haynes has made a most important discovery. Two walls of burnt brick, 3.40 metres high, 16.32 metres long and 7 metres from each other, were built out into the temple courtyard, and this causeway was filled in with crude bricks and formed a broad roadway leading up to the tower. The whole temple enclosure is surrounded by a massive wall, of which more than 30 courses are still visible.

The arrangement of this temple and tower of Ur-Gur bears a most striking resemblance to the early Egyptian pyramids, especially Medum and the stepped pyramid of Sakkara, while the causeway recalls that of the second pyramid of Khafra, which connects it with the so-called temple of the Sphinx. The question often suggested by archaeologists has been, Were these stepped pyramids connected with the temple towers of Chaldea or borrowed from them? There is now, however, a possibility of our reversing this question, in the light of these discoveries at Nippur. The pyramid we know was but an elaboration of the Mastaba, and the resemblance between these and the towers at Ur and Nippur is most striking. Dr. Hilprecht and Mr. Haynes maintain, upon very good ground, that Ur-Gur was the first to build these ziggurats, and there is certainly no trace of such edifices in any of the older cities, those at Tello or Lagash and Abu Habba, the ancient Sippara, being both later. At no period in early Chaldean history was there so close a contact between Egypt and Chaldea as during the dynasty of Ur-Gur Dungi and Gudea of Lagash. These rulers, as we know from their numerous inscriptions found at Tello by M. de Sarzec, were in constant communication with Egypt by sea and through the Sinaitic peninsula. It was from this region that they obtained the hard diorite and porphyry for their statues and door sockets. The statue of Gudea, seated and holding the plan of a temple on his knees, is most Egyptian in character, the attitude resembling that of statues of Khafra and Menkara; moreover, the scale engraved upon the tablet gives the Egyptian and not Chaldean cubit. Indeed, as Mr. Boscawen has pointed out, the statue of Gudea, the architect, with the plan on his knees bears a most striking resemblance to the Egyptian figures of Imhotep, the Egyptian god of mathematics, who may be regarded as another form of Pthah the "architect." In the face of this evidence from Nippur we may have to reconsider the question of Chaldean influence on Egypt, and, indeed, possibly reverse the old theory. The tower rests upon a massive brick platform of crude brick. Excavations conducted below this revealed the existence of a second pavement of much finer construction, being built of kiln-burnt bricks of great size, the dimensions being 50 cm. square and of great thickness. Nearly the whole of these bricks were inscribed, and bore the stamps of Sargon I. and Naram-Sin, his son, and its date, therefore, is just a thousand years prior to the buildings of Ur-Gur, namely, B.C. 3800. From the inscriptions of these kings we know that they both built large portions of an older temple of Mullil, for the bricks bear the inscription, "builder of the temple of Mullil," and dedicated a number of vases to the temple inscribed with their legends. These buildings have been entirely removed, and the surface of the vast platform levelled for the reception of the edifices of Ur-Gur.

Of the old temple there is evidence afforded by a discovery to which we shall shortly refer. Proof, however, of the great buildings of Sargon and his son is afforded by some excavations to the north-west of the temple. Here was a line of mounds which marked a rampart, and Mr. Haynes in 1895 cleared a portion of it and unearthed one of the most extraordinary pieces of masonry ever discovered. The foundation consisted of a solid bed of clay mixed with straw and puddled down, resembling some of the constructions found by Dr. Schliemann at Hissarlik. Upon this foundation and plinth was constructed a solid brick wall, 52 feet in thickness and rising to an unknown height. The builder of this wall was Naram-Sin, whom so many have regarded as a mythical king. It is probable that this rampart formed also a broad roadway round the city, and it may possibly, as Mr. Haynes suggests, have had a row of chambers in its upper part. A similar wall, but less than half as thick, was found by M. de Sarzec at Tello.

Directly to the south-east of the great tower and close to the great rampart Mr. Haynes discovered a chamber 11m. long, 3.54m. wide and 2.60 high. As there was no doorway it was evidently a vault entered from above. Its floor rested upon the platform of Naram-Sin, and it formed a communication between the two strata. The inscribed bricks proved it to have been built by Ur-Gur. What was its purpose is explained by the discovery of a second chamber of the same kind immediately below it. In this second chamber a brick stamp of Sargon was found embedded, and broken stamps and some few tablets were found in the room. The explanation is now easy. Round the walls ran a narrow shelf, on which some tablets and brick stamps were found. The chambers were the archive chambers of the temple; the smaller one that of Sargon, which had been partly restored by Ur-Gur, while the second was that of the king, built up to the level of his own pavement.

It is clear that at some time between the time of Ur-Gur, B.C. 2800, and the rise of the Kassite dynasty B.C. 2200 the archive chamber had been broken into and large numbers of objects carried away and the rest broken and scattered. There can be little doubt that this disaster took place during the terrible Elamite invasion in B.C. 2285, when all the principal temples were pillaged and their treasures carried to the Elamite capital. We have a proof of this afforded by a small disc of agate found in the ruins, which bears on one side a dedication by Dungi to Mullil, and on the other a dedication by Barnaburyas, B.C. 1400, which states that it was taken from "the Palace of Susa, in the land of Elam." The amount of *débris* from the pavement of Naram-Sin to the top of the mound is 11 metres in height, and this, we know, took close on 4,000 years to accumulate. Mr. Haynes, encouraged by the success of his work in the upper stratum, proceeded to excavate to reach the virgin soil, which he did at the depth of 9.25 metres, passing through the *débris* of ruined buildings, accumulations of broken pottery and fragments of inscribed stone objects and well-constructed drains. These remains prove the existence of at least two temples below the pavement of Naram-Sin, which at the most rapid rate of *débris* accumulation cannot be assigned to a later date than between six and seven thousand years before the Christian era. This lowest stratum has been much disturbed and the buildings pillaged; still sufficient remains to reveal to us earlier phases of Babylonian civilisation than we have ever seen. The first structure discovered was an altar of sun-dried bricks, 4m. by 2.46. The upper course had a rim of bitumen, and upon the altar was a large deposit of white ashes. Round the altar was a low wall marking the sacred enclosure. Outside of this enclosure we found two immense vases of terra-cotta. These great specimens of early pottery were each 63.5 centimetres high, and decorated with rope pattern. We have here in this simple, sacred precinct the germ from which sprang the great temples of Chaldea—the altar, with its temenos, entered only by the priest, and the two great vases for purification, replaced in after times by the greater and lesser *absu*, placed before the temples. A somewhat similar construction was discovered at Sippara, but its archaeological value was not recognised. South-east of the altar was found a remarkable structure, a brick platform, 7 metres square and 3.38 metres high, built of fine unbaked bricks. Round the base of this Mr. Haynes found a quantity of water vents, which indicated a connection with some receptacle below, and on sinking beneath this solid mass he found a drain passing underneath the platform, in the roof of which was the earliest known keystone arch. It is 71 centimetres high, and has a span 51 centimetres. The bricks are well baked and joined with stiff clay as mortar. Thus the priority of Chaldea in the use of the keystone arch is clearly established.

This structure was over 7 metres below the pavement of Ur-Gur and 4.57 below that of Naram-Sin, and, since there were no massive ziggurats or great temples to crumble into ruin, it must have taken many centuries to build up so great a mass of *débris*, and an estimate of from 1,500 to 2,000 years before the time of Sargon does not seem too high.

Having described the various strata of this remarkable site, it is now time to devote some consideration to the numerous monuments and inscriptions that have been recovered. The harvest has been an ample one. Over 26,000 tablets, as well as numerous inscribed fragments of vases and stelæ, have been recovered from this site. It is therefore clear we have no lack of material. It must be remembered, as we have already said, that the record chambers of both Sargon and Ur-Gur were sacked by the Elamite invaders of Kudur-Nakhunte in B.C. 2285, and this will account for so few inscribed records being found in the lowest strata. That, however, there had been numerous records of the pre-Sargon period which had been removed to the treasury of Sargon, and subsequently to that of Ur-Gur, is shown by a most important find. Under a pavement of Ur-Ninip, a king of the dynasty of Ur-Gur, were found quantities—some hundreds—of broken vases and other objects that had been votive offerings to the shrines of Mullil from the earliest times. Among these were some of the most archaic type, even more pictorial than those discovered by M. de Sarzec at Tello. Among these was a large stone boulder inscribed with a linear inscription of a king named Lugal-Kigub-Nidudu. Upon this we find a second endorsement by Sargon, written years after in arrow-headed characters. Here we have a manifest proof of the priority of this monarch to Sargon. Among these broken fragments, purposely destroyed, were the fragments of over a hundred vases dedicated by a king named Lugal-zaggi-si to the temple. From these texts Professor Hilprecht, almost at the loss of his eyesight, has constructed a complete text of 132 lines written in a most archaic character. Fragments of similar vases were found beneath the Sargonite pavement. The most conclusive proof, however, is afforded by the examination of these inscriptions along with the earliest monuments from Tello, where they are found to form a com-

plete historical series relating to affairs of which no mention is found either in the time of Sargon or after.

All of these records relate to a series of primitive wars, and form certainly, whatever their age may be, the oldest historical records known. The earliest of these is the inscription of "Eshagsagana," written in most archaic characters; this monarch is styled "lord of Kengi"—that is, Lower Babylonia, "the land of channels and reeds." In his time the chief enemy of Babylonia was the city of Kish, the modern El Hymer, whose priest ruler had entered into alliance with some fierce tribes called "the hosts of the Land of the Bow," a people regarding whom we shall have some remarks to make shortly. The first inscription records a war against them by the Babylonian king. It describes how the Babylonians "conquered the King of Kish and his ally," the evil-hearted "horde of the Land of the Bow," spoiled his city and burned his property, carrying away the statue of the king, his bright silver and his furniture which he dedicated to Mullil. The next inscription in this sequence is one of the king of "hordes of the Bow" who had had his revenge and conquered Babylonia. This inscription is engraved upon the vases which he dedicated to the temple. It begins by an ascription to Mullil, "the lord of the world," from "Lugal-zaggi-si, King of Erech, the son of Ukus, high priest of the Land of the Bow." Thus we see that the conqueror had established himself in the ancient capital of Erech, and from his inscriptions we learn also that he ruled in Ur-Larsa as well as in Nippur. The king then describes his empire as extending from the Lower Sea of the Tigris and Euphrates to the Upper Sea (Mediterranean), and as being granted dominion over all lands from the rising to the setting of the sun, whom he has caused to dwell in peace. How long this foreign dynasty ruled we do not know; it was, however, followed by a dynasty whose capital was Ur or Mughier. In the inscriptions of Lugal-Kigub-Nidudu found with the above we learn that he made Erech "the seat of lordship and Ur the seat of sovereignty." The closing episode of this first of wars is supplied by a monument discovered by M. de Sarzec at Tello, the celebrated stela of the Vultures now in the Louvre. In this monument erected by the King of Lagash, when a dynasty of kings was established after that of Ur, we have the record illustrated by sculpture of the king, who made a victorious campaign and utterly defeated the "hordes of the Land of the Bow."

After this, neither in the campaigns of Sargon nor his son, nor in any chronicles of the Babylonian empire, have we any record of these people. Who were they, then? Professor Hilprecht has put forward in a most dogmatic manner a theory that they are to be identified with the Semitic tribes of North Mesopotamia, and that the "City of the Bow" was Harran. He cites no ancient authority, no pre-Sargonic mention of Harran, but only a statement of Albiruni "that Harran was built in the form of a crescent moon," and that the plan of the ruins resembled a bow. It is surprising to see so brilliant a scholar using so feeble an argument. It is rather to the plains of Central Mesopotamia and the lowlands between the Tigris and the Kurdish mountains that we must look for the home of these nomadic warriors. This region was always the home of warlike nomad tribes, and the people of the Bow only preceded the host of the Manda, or Barbarians—the Gaim of the Hebrews—who, until the fall of the Babylonian Empire, were the dreaded foes of the Chaldeans. As to their Semitic character there is every reason to regard them as akin to the Sumerian. There no doubt was a variety of tribes among them, but their inscriptions are written in Sumerian and there is only one word with a suspicion of Semitic origin, and on this no argument can be based. It is enough that through the Sumerian they have restored to us the earliest chapters of the world's history. Indeed, the style of Professor Hilprecht's otherwise excellent memoir is not such as commends itself to scholars. No doubt he is making known the greatest discoveries of modern times, but there is no need to substitute personal dogmatism for scientific facts. It is waste of time to advance on slender basis theories which have to be corrected in subsequent parts.

We have been able to give only a brief account of the wonderful work of this campaign, which reflects so much credit on its organisers, and above all on Mr. Haynes. For thirty-two months he lived alone among the wildest Arab tribes in Mesopotamia, in an atmosphere of fever varied with cholera. One determined, but fortunately unsuccessful, attempt was made upon his life; yet amid all these surroundings he lived and did the work of three men. It is no over-praise to say that Mr. Haynes is justly entitled to take his place in the front rank of explorers along with those who have restored to us the first chapters of the world's history.

At Solano, in the province of Ciudad Real, Spain, the wall of a church fell in, killing nine children and injuring several others.

THE LIMITS OF SCULPTURE.

SCULPTURE being the art of conveying ideas by means of form only must of necessity reject, as irrelevant or inexpressive, all those objects whose chief charm or power is derived from that other main ingredient in nature, colour. Not only this; it must so select and arrange its lines or forms that they shall tell thoroughly to their purpose unaided by it, and this power in them is gained not by servile imitation, but by a study of their principles. In nature the two, form and colour, are blended together to carry out one purpose; but the latter is often so predominant over the former, that the eye becomes satisfied with the impression received from it alone, making no inquiry beyond. This is strongly illustrated in the plumage of birds, and the colour of insects or flowers, whose brilliancy is such as almost to obliterate from the mind the remembrance of their shapes. Sculpture, however, has but one of these means in her power, and to this one she must apply all the force she can, to accomplish what in nature is effected by the two combined.

In looking at nature, the eye never questions the correctness or possibility of any of her forms. Reason satisfies us, without effort, of their truth, if not always of their beauty; where the mind can see and comprehend the position or action of a part, it takes the rest for granted, and acknowledges at once the presence of the whole. Not so, however in art; here the eye, conscious that it is looking on the work of human hands, liable to error, becomes suspicious, and everything must in consequence be so defined as to leave little or nothing to imagination, and satisfy it, not only of the completeness as a whole, but of the proper proportion of each distinct part.

Lines and forms, the medium through which sculpture works, have certain meanings attached to them, even in their most simple and primitive character, dependent, perhaps, upon the laws of gravitation. Thus, a perpendicular line is expressive of life or fixedness, a horizontal one of sleep or death, a diagonal one of action or volition. Hogarth was the first to define the serpentine line as the one of grace, from its partaking, perhaps, of some portion of all the other three; and from the pleasurable sensation the eye experiences in travelling undisturbed along its ever-varying and gently-changing surface. Among serpentine lines, those which undulate slightly, departing but little from the straight line, are indicative of easy and elegant motion; while tortuous or angular ones betray strong and powerful, quick and animated action. Parallel or straight lines, from the sameness of sensation produced, have a tendency to create weariness, unless interrupted by stops or resting places, on which the eye can pause in its otherwise monotonous course, while sharp rectangular ones are apt to offend, from the sudden exertion necessary in the visual organ, to enable it to alter abruptly its direction. Forms have again their meaning derived from the same laws. The pyramid or cone, when standing on its base, impresses the mind with the feeling of firmness or stability; while, when on its apex, it conveys the idea of lightness or instability; and the same, when diagonally placed, expresses swiftness, assuming as it does the shape of the arrow head, and the general form of all animals whose predominant property is speed. There is in nature, amidst all her endless variations, a constant approximation to geometrical shapes, that is to say, to shapes one-half of which reflect the other. The world itself is nearly round, no animal in it is created that cannot be divided into two similar halves. The star in the heavens, by its rays, becomes almost regular in its form, while the star-fish on the shore is guided by the same law; the tree, wild as it appears, shows the same disposition in its growth. The poplar is the elongated oval, the fir the cone. Gather a branch of the myrtle and every leaf has its opposite; the flowers are made up of parts radiating from a centre and tending to one simple and nearly geometrical whole. Forms, unmeaning when single, become, when united in the kaleidoscope of nature, pleasing to the eye, as well as regular and geometrical in their character. That positive regularity of form is never attained in nature is neither a proof of her weakness, nor of the absence of the principle. He who so made his works that, while each should be subservient to its individual purpose, the whole should be agreeable to the eye of man, was too wise to do that which would have destroyed one of their chief charms, variety. This law is not intended to create monotony, but as the key-note for preserving harmony amidst all the music of creation.

The sculptor attends to these rules, he selects the lines which best express the fixedness or motion, the life or stillness, that he may require; he arranges his figures or groups in shapes that are in themselves indicative of their character or feeling; he goes near to regular forms and so obtains order, but at the same time takes warning from nature not to spoil variety by too near an approach. Regularity of arrangement, however, is admissible in sculpture in a greater degree than it is found in nature, for sculpture may be said to be the twin-sister to architecture, being ever found more or less associated with her. Hence, by partaking somewhat of the formality of the latter, she unites herself to a certain extent in sentiment with her; while

by her greater departure from positive geometrical forms and her nearer approach to those of nature, she becomes the connecting link between the two. What we have just explained is well illustrated in the antique group of the "Laocoon and Sons," in which an almost endless variety of tortuous lines expresses the strong action caused by the agony; while the placing of the two sons, somewhat formally, one on each side of the father, preserves due order amidst all the horrors of the scene.

Sculpture is an art intended not merely for the gratification of a day, but for the pleasure and instruction of ages. Everything, therefore, which relates only to the fashion of a moment, or that is in contradiction to the never-changing principles of nature, is in it so much wrong. The ancient Greeks made their figures nude or partially covered with drapery—not silk, satin, velvet or cotton, but with drapery, cut neither into coat, waistcoat nor trousers, but hanging according to the natural laws of gravitation, which regulated its folds then as it does now. The waists of their figures are not short, like those of the last generation, nor long, like the present. No part is unnaturally compressed or increased beyond its proper proportions. The divisions of the human frame are left where nature intended them to be; man walks forth from their hands as he first walked forth from the hand of his Maker, and so long as his laws remain the same, so long will the reputation of these great works last.

The only legitimate exception to this rule is portraiture, a species of sculpture which, while it acknowledges tributary obedience to the general laws of the art, asserts for itself the right of making regulations of its own, for carrying out more effectually its particular purposes. So much discussion has taken place, and such a variety of opinion exists on this subject, that it may be well to devote a few lines to it. Sculptors who draw their inferences and rules of art entirely from ancient examples contend that all indications of the dress or manners of the period to which the person represented belongs should be obliterated in a portrait-statue; that costume should be thrown aside, and scarcely aught, save the face, be literally transferred from nature to the marble or bronze. This is called idealising a statue, and idealising it is, there is no doubt, in one way of speaking, for but little of the individual character of the original enters into the composition. It is, however, a mistaken view of the question; for the primary object in portraiture, whether in painting or sculpture, must be to record, in a pleasing and appropriate manner, the personal resemblance of the original; to hand down to posterity the bodily form, in which is contained those mental powers that make him admired or beloved; to give to the eye permanently that which no history or biography will be able hereafter thoroughly to convey to the imagination. For the accomplishment of this he must be represented surrounded by those circumstances that mark the time in which he lives, and the employments in which he is engaged. Suppose, for the sake of argument, all portrait-statues to be made after the fashion above alluded to, as they too frequently are when entrusted to artists who are too bigoted to the ancient practices of their profession to apply the powers of reason to their works—suppose, we say, all portrait-statues to be made nude, or clothed only with simple drapery, which neither marks age nor country, and that they are at some future period recovered from the ruins of a decayed nation, as have been the statues of ancient Greece, with scarcely anything to distinguish them one from another, beyond perhaps some vague allusions to them found in the works of contemporary writers, or, at the best, a stray medal or coin that appears to bear some faint resemblance to them—what will enable the antiquarian or historian of that future age to distinguish between the representation of a Chaucer or a Spencer, a Newton or a Bacon, a Shakespeare or a Milton, a Pitt or a Peel, a Watt or a Stephenson? There is besides an inherent character in portrait faces which no ingenious treatment in sculpture can completely harmonise with that general representation attempted in what is conventionally called the classical style. By removing the peculiarity of the general form and depriving the figure of its dress and customary accessories the individuality of the face becomes more apparent and incongruous. The work under this sort of treatment amounts at the best but to a sort of bastard idealisation.

It is not intended in this argument to advocate positive, literal copying in matters of costume. A statue is not erected to commemorate the dress, but the man; it is sufficient, therefore, if the former be so indicated as to give the general impression of belonging to its wearer and his times. Such peculiarities in it as are unimportant or offensive to good taste, or that detract from the broad treatment of the work, should be omitted or judiciously concealed. An artist of right feeling finds no great difficulty in this, though perhaps nothing serves so much to distinguish his work from that of inferior men as due attention in this particular. There are many kinds of modern dresses, as well suited to sculpture as the most simple drapery, such as the robes of our princes and peers, our judges and clergy; and it is rarely that an opportunity is wanting in a

statue of selecting one or other of these. Even the ordinary modern dress worn in our streets may, by a little modification and treatment, be so approached in marble as to give a general impression of identity, and yet not be ludicrous or offensive to those who may hereafter have to look at the work when the fashion shall have changed or entirely departed. Were a proof wanting that this is the correct method of solving the question, we might quote the opinion of Flaxman, as shown in his works. Though the most imaginative sculptor England, or perhaps the world, ever produced, his portrait-statues are singularly literal; in fact, if they have a fault it is the too close adhesion to the detail of modern dress; evidently showing that he felt the sound judgment of not departing from those things that mark identity of person and period. His figure of Sir Joshua Reynolds in St. Paul's Cathedral is an instance of judicious choice of costume, and will bear comparison with most works of the English school; and his statue of Pitt is another instance of close attention to this point, notwithstanding which it is a thoroughly characteristic work, simple and elegant, dignified and statesmanlike.

It is generally felt that good ideal sculptors rarely send forth successful portrait-works. The reason is obvious, though not often inquired into. The general system of their training is in opposition to the attainment of the power necessary for producing strongly characteristic likenesses. They are taught in their studies to avoid all that is individual, and to extract beauty from nature by sifting and selecting from her works that which is general or universal in its application. In ideal works, character, it is true, must be mixed up with beauty, but that character must be of general nature, as illustrated by classes; and, as such, is perfectly distinct from that necessarily strong feature in good portraiture—individuality. This individuality the portrait-sculptor, instead of rejecting, has to seize strongly upon, to portray in his statue, and even to increase in power, that it may make a lasting impression on the spectator. This he must do, not by exaggeration of form, manner, attitude, or expression—for that of course would be caricature—but by depicting the person under suitable circumstances, and engaged in employments appropriate to him, and that tend to bring forward his best and most striking expression and attitude. The artist must select, too, from the component parts of individuality such as are pleasing and to the purpose, and reject such as are otherwise. This is what is vulgarly called flattery, but it is no departure from the truth otherwise than in not telling the whole of it. The peculiarities, whether personal or mental, are not changed; it is merely that the best only are brought out to view and the others veiled from the sight, but gently hinted at or, maybe, altogether omitted.

It will be easily seen, therefore, that the requisites for success in the two walks of art are somewhat different, if not wholly opposed to each other, owing to individual character and abstract beauty being such essentially contradictory qualities, as is shown by the circumstance that the one may be exaggerated and so become caricature, while the other is incapable of being either conceived or represented in excess.

Material must always have a powerful effect in regulating the style or manner of sculpture, and in limiting its efforts. To the ponderous blocks of syenite and granite, so unmanageable to the workman, we are indebted for many of the peculiarities belonging to Egyptian art. The beautiful marble of the Greeks, capable of delicate finish, and yet possessing within itself the elements of strength, helped them in a measure to the execution of their light, elegant and lifelike figures. The softer materials employed by the Gothic sculptors of the Mediaeval ages obliged them to resort to long draperies and other contrivances to render their statues durable. A due consideration of the material in which a work is to be executed is one of the primary studies of the sculptor, and affects his design as well as his execution. An attempt to exceed the limits which that material puts upon him may be considered not as a proof of genius, but rather as a misunderstanding of his art. For instance, if his work be intended for marble, he will endeavour, while he retains the lightness and elegance necessary for his subject, so to arrange the parts that they shall be durable and at the same time capable of being with tolerable facility carried out in execution. While he attempts the introduction of nothing that cannot be perfectly expressed in such material, he will often strengthen many features of his work when he wishes them to tell forcibly, even beyond what he is justified by nature, knowing that otherwise their effect must be weak in consequence of the substance being colourless and semi-transparent. To this, which may be considered as a question partly of light and partly of material, the English sculptors scarcely give due attention; they are accustomed to work their figures and groups in studios where the windows are constructed so as to produce upon them strong decided lights and shades, and the result is that when they are brought out into the broad open air their forms are found to be insufficiently defined, the white pellucid marble absorbing and amalgamating the little contrast of light and shade which they receive. The style of touch in

the English school is more suited to painting than to sculpture, and the general appearance of the surfaces may be compared, criticising them severely, to what by judges in horse-flesh is termed "gummy." The foreign sculptors, however, seem to calculate better on the changes of light and shade which their work has to undergo, as well as on the nature of their material; and in this respect are decidedly superior. If the work be intended for bronze, the sculptor is free from fear as to the fragility of parts, and can proceed without any regard to that circumstance, but he has others connected with his material to influence him; he knows that his statue will eventually be of a dark opaque colour, so dark that often, when standing between the sun and the spectator, little except the marginal outline will be visible; he must therefore so design it that it shall tell effectively, unaided by aught save that outline, the internal details or minutiae becoming comparatively valueless, except that so far as they help to make up the boundary line from different points of sight. Many things therefore are forbidden that would probably in the white marble help to give interest, but which in the dark bronze would detract from that clear definition of form which must always be apparent in every view.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

CHATSWORTH HOUSE was this year selected for the excursion, which took place on Saturday last, of the members of the Sheffield Society of Architects and Surveyors. An early start was made, and the drive to Baslow was by the direct road, luncheon being ready at the Devonshire Hotel when the party arrived. The Duke of Devonshire placed the whole of Chatsworth and its grounds at the disposal of the members, and there was no check whatever upon the party seeing anything that could interest them as professional men and lovers of all that is beautiful and rare in art. Mr. Gilson Martin, F.S.I., his Grace's steward, met the members at the main entrance and accorded them a hearty welcome. Mr. B. Bagshawe, who is a "lay" member of the Society, was appointed cicerone, and fulfilled the duties of his office admirably. He has a rare knowledge of Chatsworth, of its history, its architecture and its many treasures, and without loss of time was able to conduct the party to places of the deepest interest to them. He was ever ready with explanation, suggestion and reminiscence, and his able guidance made the visit doubly enjoyable. Peculiarities of the stonework at the entrance having been commented upon, a visit was made to that portion of the house usually shown to the public, and here there was much to admire, though to many the sights were no new pleasure. The members were then privileged to visit the library, where Miss Martin was in readiness to display the many treasures it contains. A long stay was made here, and among the numerous valuable books examined were Claude Lorraine's "Liber Veritas," several of the famous Inigo Jones's sketch-books, one including a diary of his stay at Rome, and another containing many exquisite designs—some coloured—for masque costume, &c.; early Caxtons and the first book printed in the English language, valuable illuminated books, a curious volume of surveys of the Cavendish estate at the end of the sixteenth and the early part of the seventeenth century, early plans of Chatsworth House and sketches and manuscript memoranda of Watson, the person principally engaged on the carved stone and woodwork at Chatsworth at the end of the seventeenth and the beginning of the eighteenth century. Leaving the library, the grand suite of private apartments was traversed, and an opportunity was given of examining the magnificent works of Holbein, Tintoretto, Rembrandt, and other great artists of their time. A move was made for the two galleries containing the most valuable collection of original works by old masters in the possession of any private individual. None of the great Italian, German, Flemish, French, Venetian, Spanish and other schools are unrepresented, and the paintings were a revelation to most of those present. Amongst them are the works of Raphael, Michel Angelo, Rembrandt, Rubens, Leonardo da Vinci, Poussin, Claude, Salvator Rosa, Correggio, Luca Signorelli, Vandyke and many others. The pictures, of course, are not of large size, and the two galleries are filled with them. Hours would be insufficient to make a real inspection of the grand collection, and it would take days to observe and study them as they deserve. The late Mr. Reid, of the British Museum, made a careful catalogue of the collection in recent years, and many of the more valuable drawings were autotyped years ago by Messrs. Braun, of Paris, from whom facsimiles are still obtainable. Among other rooms visited were two private ones, containing a collection of exquisite water-colour drawings, principally beautiful examples of David Cox and William Hunt. The famous sculpture gallery also proved most interesting. Here the vice-president, Mr. Joseph Smith, proposed a hearty vote of thanks to the Duke of Devonshire for the privilege he

had accorded the members, to Mr. Gilson Martin for his kindness in personally conducting the members through the house, and to Miss Martin for the manner in which she had placed the treasures of the library at the disposal of the visitors. The resolution was seconded, supported and warmly carried, and Mr. Gilson Martin, in reply, expressed the pleasure it had given his Grace to grant permission to view the house, and to him (Mr. Gilson Martin) to accompany the party. The admirable services of Mr. Bagshawe as cicerone were also cordially acknowledged.

Afterwards the gardens, with their many artificial wonders, and the electrical apparatus, for which water power is utilised for lighting the whole of the house, were examined. The fountains, including the Emperor, which throws a jet of water 270 feet high, were playing in honour of the visitors, but there was not time to remain in the cool air in their vicinity, as there had to be a long discussion regarding the exterior of the house and the cheap rate at which much of the beautiful carving was executed. The tour concluded with a visit to Queen Mary's Bower, and many were the opinions hazarded as to the time of erection and object of the strange, moat-surrounded building. No satisfactory conclusion was come to, but there was general agreement that the building was erected before the time of Queen Mary. This concluded the tour, the members having devoted about 3½ hours to their work of pleasure.

TESSERÆ.

King John's Tomb, Worcester Cathedral.

THE body of the king, royally attired, was conveyed to Worcester; over his head was placed a monk's cowl, as a sort of cover for all his sins and a passport to heaven. He was interred between St. Oswald and St. Walstan, whose graves are in the chapel of the Virgin, at the eastern extremity of the cathedral. Thence, in all probability, his remains underwent translation to their present situation, before the high altar in the choir. The effigy of John, carved in grey marble, which forms the superstructure of his present tomb, was originally the lid of the stone coffin that contained his remains, and in its first position must have been placed on a level with the floor of the building within which he was interred. His head is adorned with a crown of state, and supported by two bishops, undoubtedly intended for Oswald and Walstan, between whose remains he, as before mentioned, actually reposed. He is represented as wearing a dalmatic of crimson, lined with green, the neck and cuffs edged with a gold and jewelled border; his tunic is yellow, or cloth of gold; he is girt with a belt; on his hands are jewelled gloves, a ring on the middle finger of the right hand, which supports a sceptre, while his left grasps a sword; he wears red hose, golden spurs; his feet have on them black shoes, resting on a lion. Valentine Green, F.S.A., the historian of Worcester, published a pamphlet, giving a very interesting account of the opening of the tomb of King John, on July 17, 1797. The state of the king's mortal relics showed that they had been at some previous time disturbed, and seemed to favour the conjecture of their having been translated from the lady chapel in the cathedral into the choir, most probably about the time of Henry VII. The skull was found turned completely round, and presented what anatomists term the *foramen magnum*, or aperture through which the spinal marrow passes. The upper jaw lay near the right elbow. The agreement of the dress on the body with that of the effigy on the tomb was very remarkable, and shows, as in the instance of Henry II.'s figure, that these effigies very faithfully represented the defunct as he lay in state. John had, however, no crown on his head or gloves on his hands. In the place of the former was found the celebrated monk's cowl, confirming the minute accuracy of the chronicles. This sacred envelope fitted the head very closely, and had been buckled under the chin by straps, parts of which still remained. The body had been covered with a crimson robe of damask, of strong texture, reaching from the neck to the feet, as in the effigy. Part of the embroidery was still perfect near the left knee. His left arm was bent towards his breast, and the hand had grasped a sword, in the same manner as the figure on the tomb; the cuff of this arm still remained lying on the breast. The sword was much decomposed, and its parts found at intervals down the left side; the scabbard was much more perfect. The covering of the legs (the precise nature of which was not ascertained) was tied round the ankles. These were probably the red hose seen in the effigy.

Sir Henry Raeburn's Daily Life.

He rose at seven during summer, took breakfast about eight with his wife and children, walked into George Street and was ready for a sitter by nine; and of sitters he generally had for many years not fewer than three or four a day. To these he gave an hour and a half each. He seldom kept a sitter more than two hours unless the person happened—and that was

often the case—to be gifted with more than common talents. He then felt himself happy, and never failed to detain the party till the arrival of a new sitter intimated that he must be gone. For a head size he generally required four or five sittings; and he preferred painting the head and hands to any other part of the body, assigning as a reason that they required least consideration. A fold of drapery, or the natural ease which the casting of a mantle over the shoulder demanded, occasioned him more perplexing study than a head full of thought and imagination. Such was the intuition with which he penetrated at once to the mind that the first sitting rarely came to a close without his having seized strongly on the character and disposition of the individual. He never drew in his heads or indeed any other part of the body with chalk—a system pursued successfully by Lawrence—but began with the brush at once. The forehead, chin, nose and mouth were his first touches. He always painted standing and never used a stick for resting his hand on, for such was his accuracy of eye and steadiness of nerve that he could introduce the most delicate touches or the utmost mechanical regularity of line without aid or other contrivance than fair off-hand dexterity. He remained in his painting-room till a little after five o'clock when he walked home through the Edinburgh streets and dined at six.

Westminster Abbey.

The incorporation at Westminster of the palace and abbey from its earliest days is a likeness of the English constitution, a combination of things sacred and things common. The abbey is secular because it is sacred, and sacred because it is secular. The vast political pageants of which it has been the theatre, the dust of the most worldly laid side by side with the dust of the most saintly, the wrangles of divines or statesmen which have disturbed its sacred peace, the clash of arms which has pursued fugitive warriors and princes into the shades of its sanctuary, even the traces of Westminster boys who have played in its cloisters and inscribed their names on its walls, belong to the story of the abbey no less than its venerable beauty, its solemn services and its lofty aspirations. Go elsewhere for your smooth polished buildings, your purely ecclesiastical places of worship—go to the creations of yesterday, the modern basilica, the restored church, the nonconformist tabernacle, but it is this union of secular with ecclesiastical grandeur in Westminster Abbey that constitutes its special delight. It is this union which has made the abbey the seat of the Imperial throne, the sepulchre of kings and kinglike men, the home of the English nation, where for the moment all Englishmen may forget their differences, finding underneath its roof echoes of some memories dear to each.

Thomas Stothard's Narration of his Early Days.

My father was a native of Stretton, near Doncaster; he came to London while a lad, and when he married took a sort of hotel in Long Acre, which was much frequented by coach-makers. I was born there in the month of August 1755. I was an old child, and a sickly and ailing one; my father, anxious about my health, sent me when only five years old to his brother in York, but as he lived in a close part of the city I was removed to Acomb, a small village two miles north of York, and put under the care of an old douce Scotch lady—a sound Presbyterian, who loved to keep her house in order and all that was in it. As this was the Kensington Gravel Pits of York I soon began to grow strong, and I remember that I also grew solicitous to be doing something. I soon found employment, which has now afforded me full seventy years' pleasure—I became a painter. This came rather curiously about. My Scotch friend had two sons in the Temple, London, who had sent her some of Houbraken's heads, with an engraving of *Blind Belisarius* and other prints from the graver of Strange; as they were framed she had them hung up in a sort of drawing-room, and rarely allowed any one to look at her treasures as she called them. One day I ventured to follow her into this sanctuary; she was pleased with the earnest looks with which I regarded the heads and groups, patted me on the head, and said I should often see them since I seemed to like them so much. I became an almost daily visitor to the room, and I began to wonder how such things were done; I was told they were done with pencils. Though the old lady told me this she little expected the result; in short, she missed me from her side one day, and found me standing on a chair trying to imitate with a pencil one of the heads before me. She smiled, clapped my head and bade me go on, adding, "Thomas, ye are really a queer boy." I did little else now but draw, and I soon began to make tolerable copies. I lived at Acomb till I was eight years old, when I left my old Scottish dame with tears in my eyes and went to school at Stretton, the birthplace of my father. I continued drawing, and even attempted to make sketches from life. Some one told me that engravings were made from paintings in oil-colours; I longed to see a painting, and shall never forget the delight with which for the first time I looked upon one. I resolved to paint in colours, and wrote

to my father to send me some. I was, however, too impatient to wait their coming, but going to a cart and ploughwright, I begged black, red and white oil-colours from him, and commenced to make a picture. I painted a man, I remember, in black paint, and then tried with the red and white to work it into the hues of life. It was a sad daub; I still persevered, and soon learned to handle my brush with more skill and lay on my colours with better taste. I was soon afterwards removed to London, where all manner of facilities abounded—you know the rest.

The Equestrian Groups on Monte Cavallo, Rome.

In the ruins of the Baths of Constantine were found the two grand colossal groups of a *Young Man and Horse*, which now stand on the summit of this hill, and from which are derived its modern name of Monte Cavallo, an appellation which is still the most in general use, although a feeling of Classical taste has revived the ancient one of the Quirinal. If the inscriptions on these statues be genuine they are the works of Phidias and Praxiteles; and the antiquarians, who always contrive to blunder even where it would seem to be impossible, by an absurd anachronism pronounced them to be rival groups of these two great masters, representing *Alexander and Bucephalus*, although the Athenian sculptor was dead before the Macedonian hero or his horse was born. They are now supposed to represent Castor and Pollux, and are still believed to be by Phidias and Praxiteles. They are certainly extremely spirited and grand in their conception, but destitute of finish; and more than all, of that high pre-eminent perfection which ought to mark the works of the first of sculptors. Their resemblance is so close in style that one would be tempted to consider them works of the same age, if not of the same artist; and they approximate so nearly in design that one might almost be permitted to hesitate before pronouncing them to be productions of masters so great, yet so totally dissimilar. It must at least be acknowledged that Praxiteles has made but a very slavish copy from the group of his great predecessor. But any one who has studied the undoubted works of Phidias in the Elgin marbles, or felt the beauty of the masterpieces of Praxiteles, even in their ancient copies, will perhaps require something more to convince him that these groups are the work of either of these great masters than an inscription the antiquity of which is dubious, and which, even if admitted, may, like half the inscriptions on ancient sculpture, be false. It scarcely seems that their excellence is sufficient to have induced the Romans to bring groups of such colossal size from Greece; neither is it probable such a circumstance would have passed unnoticed by ancient writers; and if they were executed at Rome it is certain that Phidias, at least, never came there to make them. But, whether or not the works of these great masters, they are fine pieces of sculpture, and are placed to great advantage on the summit of the Quirinal Hill. It would be in vain now to look for its three summits, the Collis Salutaris, the Collis Mutialis, and the Collis Latiatis, since one only can now be distinguished, and which of the three that is we have no means of ascertaining.

The Study of Ancient Art.

The works of the ancients can never be studied too much, but they may easily be studied improperly. The prime object which ought always to be kept in view, as the only means by which we can ever hope to rival them, is the rediscovery, in its fullest extent, of the principle on which they were formed, which none of the moderns have yet comprehended nor probably attempted, scarcely suspecting its existence; the best of them have, in general, contented themselves with selecting some favourite figure and using it on all occasions indiscriminately, as a rule of proportion, absurdly forgetting that, if it was exactly proper in any one instance it must necessarily be more or less improper in all others. Thus, in escaping the meanness and vulgarity of common nature, they confounded all distinction of character, and became incurable mannerists, insipid or extravagant, according to their choice of a model. Nor is this the only evil to be dreaded and guarded against in the imitation of the antique statues; for though, as Rubens justly observes, we can never consider them too attentively or study them too closely; though in order to attain perfection in painting it is necessary to understand them, nay, to be so thoroughly possessed of this knowledge that it may diffuse itself everywhere (for in this degenerate age we can produce nothing like them), yet it is no less certain that ignorant painters and beginners, who make no distinction betwixt the figure and the stone, the form and the material of which it is composed, often learn from them somewhat that is stiff, crude, liney and harsh in respect to anatomy; by which, while they take themselves to be good proficient, they do but disgrace nature instead of ennobling her, losing all her warmth and feeling; and giving us marble tinged with various colours in the place of flesh. In sculpture it must be remembered that, without any fault in the work or the workman, many outlines and shadows appear hard, dense

and opaque, which in nature are softened and harmonised by the colour and transparency of the flesh, skin and cartilages, and that the lights also are extremely different from the natural, the hardness and polish of the material giving them a lustre and a sharpness which dazzles the eye and raises the surface beyond the proper pitch.

The Illumination of St. Paul's Cathedral.

SIR,—The above building was illuminated on the night of June 22 according to my method, viz. by means of searchlights placed on buildings surrounding the cathedral. It is now over two months ago that I suggested to the Dean of St. Paul's, and also the City surveyor, my system of illuminating the most conspicuous building in the City of London. The reasons why I suggested this method of illuminating the masterpiece of Sir Christopher Wren were as follows:—Firstly, the possible danger of fire by attaching electric lamps to the dome, which is a timber construction. Secondly, by lining out the cornices, ribs on dome, &c., by means of thousands of glow-lamps the grand outlines of this architectural masterpiece are cut up and destroyed. My method was to brilliantly illuminate the dome and west front by means of from 80 to 100 powerful searchlights, each of 2,000 nominal candle-power. In conjunction with a well-known and practical firm of electrical engineers I entered thoroughly into the matter, and we arrived at the conclusion that the above number of searchlights would be required to make the illumination of St. Paul's Cathedral a perfect and undoubted success. I also proposed to change colours about twenty times per minute, so as not to make the illumination monotonous. For the above purpose I submitted an estimate to the Corporation of London for 765*l*. This included the wages of workmen employed in manipulating the projectors, the cost of electric current, rent of stations and all other incidental expenses. The City surveyor informed me that the Corporation intended to do the work as cheaply as possible, and I understood that they would only illuminate the dome (according to my method) by means of from twenty-six to thirty-six searchlights, and that the expenses would be from 150*l*. to 200*l*. To my surprise, I notice in a contemporary of yours that the expenses attached to the above illumination would amount to about 1,400*l*. If I had not on May 19 last, in a letter to the *City Press*, drawn the attention of the Cathedral authorities as well as the Corporation of London to the danger of fire by attaching lamps to the timber dome of St. Paul's, this method would have been adopted, as not one person in a hundred was aware that the dome is a timber construction. I fail to see how the City authorities have done this work as effectively and cheaply as they professed, as my estimate was nearly half of what they have now spent, and they have not employed as many search-lights as I proposed in my above estimate, while the west front was not illuminated as I suggested. They refused my estimate on the plea of expense, and then they spend nearly double the amount (employing less lights) in illuminating St. Paul's Cathedral and adopting my original system. I claim to be the originator of this method of illuminating the most conspicuous building in the City of London, and, to my knowledge, my system has not before been employed in the illumination of a public building in London. I notice in a building paper (published on Saturday) that, in speaking of the illumination of St. Paul's Cathedral, they say, "It seems a pity that they did not line out the architecture in lights, &c., and that there seemed to be a needless fear of fire, &c." It is evident that the writer in the above paper is ignorant of the danger of fire by attaching electric lamps to dry timber of over 200 years' standing. Trusting that you will favour me with space for this letter, I am, sir, your obedient servant,

HENRY H. B. SANG,
Architect and Artist.

Liskeard Church Tower.

SIR,—I shall welcome *bona fide* criticisms, information or communication from you or from your readers on the letters passed between Chancellor Paul of Truro and myself re Liskeard Church tower, which you kindly published some two or three weeks ago. I would ask:—(1) Has the Chancellor power to refuse a faculty without trial or open court when no opposition is lodged against it? (2) Has he power to reject plans, sanctioned by every vestry, every public meeting, and selected by a disinterested and eminent architect? (3) Has he power to insist on our rebuilding a small semi-Norman tower

(much of this tower is of the 17th century) to a large Perpendicular nave, built long after the erection of the original tower?

This tower is admitted by several expert architects, and also by the Chancellor, to be in a dangerous condition, and that it must come down.—Faithfully yours,

J. NORRIS.

Liskeard Vicarage, Cornwall:

June 28, 1897.

In a letter to his parishioners, dated June 24, 1897, the Rev. J. Norris writes:—

I am full of hope that Chancellor Paul will yet see the wisdom of bestowing upon us—even if we are in the wrong, of which we are not aware—an open court, or giving to us a private audience, that the present friction may be removed and the former spirit of goodwill may be restored. An open court or audience would and will show where and in what the error or mistake lies. To the pure all things are pure—to the lights of justice and equity we wish to bow. There can be nothing against honest and candid discussion. We ask for no more. It would be useless applying for faculties, or of getting the best plans procurable, of spending—as we have done—much money, if the friends of the Church, who are willing to give their time, money and labour, are to be nonsuited without any trial or court.

Strange, but true, the present church was re-roofed, the lady chapel gallery re-erected, the pulpit and reading desk removed, all the stained-glass windows put in, organ gallery removed, new organ chamber built, the handsome reredos placed in its present position, the old vestry pulled down and the present clergy vestry erected and I know not what, without any application for faculties, each one and all according to Church law required such costly powers; and when we, rightly or wrongly, apply for a faculty, we are not allowed an open court or private audience. We are open to conviction. We are advised by our Bishop if we cannot accept his Chancellor's decision to go to the Court of Arches. I hope we shall do nothing of the kind.

I think the following letter, issued by Messrs. L. C. Foster and R. A. Courtney on March 12, 1892, is one of the strongest I have seen or read in favour of pulling down the present tower and the erection of a new tower:—

"There is, however, another portion of the work which your committee would like to see carried out, and that is the rebuilding of the tower. You are doubtless aware that the late Miss Pedler, who died on November 20, 1890, left the sum of 1,000*l*. towards this object, provided that within ten years of her death a new tower was erected at a cost of 3,000*l*. It will, therefore, devolve on the parishioners if they desire to secure the benefit of the 1,000*l*. to determine what course they will adopt, as if the tower be not erected, the amount will be paid over for the benefit of Truro Cathedral, and so be lost for the use of the parish. The shaky and dilapidated condition of the tower is well known, and it must be either rebuilt or a considerable sum be expended before long in order to strengthen and secure the present structure. The committee desire that a tower worthy of the church should be erected, and they believe that with the hearty co-operation of the parishioners and others, who are and have been associated with the town, that a balance of the necessary amount can be raised and the work carried out."

GENERAL.

Mr. E. Guy Dawber, of 22 Buckingham Street, Adelphi, has taken into partnership Mr. Francis A. Whitwell, and the firm will in the future be Messrs. E. Guy Dauber & Whitwell.

The New Catholic Church of SS. Peter and Paul, Bolton, was opened on Wednesday. The scheme, which the Bishop of Salford has described as the greatest undertaking in connection with any church in his diocese since he was consecrated, has cost, with a fine new assembly hall opened some time ago, something like 18,000*l*. The church, from an architectural point of view, will rank as one of the handsomest in Lancashire, the interior being rich in appearance, marble entering into a portion of the edifice.

An Archaeological Discovery of considerable interest has been made near Thermopylae, between the old barracks and the water mills. It consists in the laying bare of sarcophagi containing bones, earthenware and glass vases, bronze coins, medals, &c. It is believed that the skeletons are the remains of Leonidas's Spartans.

The Mayoress of Southport laid on the 26th ult. the memorial-stones of a new Wesleyan place of worship, to be called the Victoria Chapel. The total cost of the building will be 5,000*l*. The church will be in the late Gothic style of architecture, and will provide seating accommodation for 850 people. Messrs. Green & Brockbank, of Liverpool, are the architects, their designs having been selected in competition, and the contractors are Messrs. Duxfield Brothers, of Southport.

The Architect.

THE WEEK.

THE County Council having been invited to give evidence before the Royal Commission on the Metropolitan Water Companies, have decided upon a series of principles which it is believed will express the opinion of a majority of the Council. They are as follows :—(a) That in the opinion of the Council the water supply of the metropolis should not continue in the hands of private companies. (b) That in the opinion of the Council the undertakings of the metropolitan water companies should forthwith be purchased at the fair and reasonable value of the same, regard being had to the rights, special circumstances and obligations of the companies. (c) That the management of the water supply should be effected either (1) by the London County Council supplying its own area directly and outside authorities in bulk at a fixed price; or (2) by the London County Council supplying its own area only, and the outside authorities supplying their areas; or (3) by a new body supplying directly the whole area both within and without the county. (d) That in any case, as the County of London contains 87 per cent. of the rateable value and over 79 per cent. of the population of the whole area supplied by the metropolitan water companies, and will thus be liable for more than four-fifths of the purchase money, it is desirable that the London County Council should, in the first instance, be the purchasing authority on behalf of the population of the whole area concerned. (e) That if the undertakings of the water companies are not acquired it is essential that effective powers of control should be given to the County Council, and, further, that the position of the companies should be reconsidered and the law amended, particularly as regards their power to make and recover rates and charges and divide profits, and their obligations respecting the supply of water. It will be observed that attention is concentrated on the existing supply, and that the rights of property are fully respected. The question of increasing the supply by drawing water from other sources would be considered at a future time.

ON the 20th inst. the annual meeting of the Sussex Archaeological Society will be held in Worthing. That pleasant watering-place is not suggestive of antiquity, but in the neighbourhood there are subjects which would require not one but several days to do them justice. Sompting Church, which is to be first visited, is supposed to date from the eleventh century, and it is believed that the tower is Anglo-Saxon. But it has lost much of its character by repeated restorations. It continues, however, to be one of the most interesting churches in Sussex. Broadwater Church, which will also be visited, is transition Norman and has been carefully preserved. There are three brasses of a fine sixteenth-century monument of Lord DE LA WARR. Another church which is to be visited is West Tarring, which has a Perpendicular tower. The marble mosaics of the Apostles which Mr. BUTTERFIELD designed are still deserving of attention. The Archbishops of Canterbury possessed a palace here of which there are remains. On Highdown Hill there are some earthworks, and an experiment in excavation will take place during the visit. At Ferring the collection of antiquities discovered by Mr. HENTY will be on view. Altogether the members have a chance of spending an agreeable day amidst scenery which has many attractions.

It cannot be expected that judges are always to be of one mind in their decisions, but it becomes a serious affair when a public health Act is rendered useless because courts will not look at a subject except from one point. Glasgow is at present in the position of possessing powers to aid in the advancement of sanitation, but owing to the variance

between the courts they are of no avail. The Police Amendment Act of 1890 provides that, "If the drains be found defective, the owner of the premises shall be bound, on an order to that effect being given by the police commissioners, to carry out all necessary operations for removing defects in structure, or doing such acts as may be requisite to prevent risk to health, and, failing compliance with such order, the police commissioners may do such work and recover the expense as damages from the owner." The section seems effectual until an attempt is made to put it into operation, and then it is found that, like thousands of clauses in other Acts, it is of no avail to sanitary authorities. The Corporation of Glasgow on the strength of the section ordered the drainage of a house in Garngad Hill to be improved. The owners declined. The sanitary inspector's notice was disregarded and then the Corporation carried out the necessary operations. The work cost 80*l.* 10*s.* 8*d.* The owners declined to pay and were sued. In one Court a decree was granted for the amount. But that judgment was reversed by the judges of the Second Division. After playing a sort of game of legal seesaw in various courts the case was brought before the House of Lords by the Corporation. Their lordships pointed out that the Corporation did not so much "remove defects" as construct a new drain. But then the question arose, How was it to be discovered that the new drain was solely used to prevent risk to health? The Court of Session had not imparted information on that point. Without some knowledge of local conditions it was impossible for their lordships to say how far risks to health were removed. The case was accordingly sent back to the Court of Session in order that it could be stated whether the work was necessary to prevent those risks, and until a decision on that point is given the owners of property can have their way and neglect remedies which jeopardise the sanitation of Glasgow.

IN the interim report of the Departmental Committee on Electrical Generating Works which appeared this week, the following suggestions are given for diminishing the risks from underground mains :—"Concentric mains are often employed with a central high-pressure wire or cable, and an external group of wires insulated from the central cable. The outer wires are in general insulated again, and the whole is often enclosed in a lead tube. If the outer conductor is efficiently connected with earth at the generating works, no part of it will attain a dangerous pressure, and the risk of handling such a cable is greatly reduced. Transformers and the metal cases in which they may be enclosed, if not efficiently connected to earth, are a source of danger in the event of 'running to frame,' or of any deficiency in the insulation of the high-pressure wire or cable. If there is any moderate insulation leakage the earth-connected case cannot become charged; or if the insulation fail, and the high-pressure main becomes connected with the casing, the extra strong current resulting will blow the fuse in the transformer or its chamber, or at the central station, and disconnect the faulty part from the circuit. So long as no highly-charged metal is exposed and the conditions indicated are correctly fulfilled, it would appear almost impossible for accidents to occur to men at work outside the transformer casing. By efficient earthing is meant metallic connection to some good conductor which is in contact with damp soil over a considerable area. An earth cannot be considered efficient unless, under all weather conditions, in case of accidental contact with metal charged to high pressure, it will secure the passage of a current sufficient to blow the fuse employed for the protection of that metal. The best earth often available is the system of cast-iron pipes, through which the cables pass, provided all the joints are metallic. A mere bolt or rod in brickwork, concrete or in the ground, especially when that is liable to become dry, would be useless as an efficient earth in the case of metallic connection with high-pressure supply, but it might be sufficient to discharge the very small leakage that would occur with sound and, ordinarily speaking, perfect insulation. Transformers become warm in working, and thus the chambers, especially if well ventilated, are apt to become very dry."

CANTERBURY CATHEDRAL.—II.

CANTERBURY Cathedral is by some visitors supposed to exemplify an architectural climax and for the greater honour of St. THOMAS À BECKET. The choir, it is said, is raised several feet above the nave, the altar is higher than the choir, Trinity Chapel is higher than the presbytery and BECKET'S Crown dominates all. If, however, the last division be called simply a corona, apse or circular chapel, without any reference to the Martyr, then the theory of a climax will be less apparent. But the ascribing of the part that closes the noble perspective to him is easily understood. Although the memory of the archbishop pervades, as it were, the entire cathedral, there is, strange to say, no portion of it which is dedicated to him. There never was a BECKET Chapel in the Cathedral, and at present we can see no monument to him. When CROSS'S painting of the murder was hung in the "Martyrdom" a few years ago, it was considered to be a necessity, for it helped to indicate where the deed took place. It was not until half a century after the archbishop's death that a shrine for his remains was prepared, and then it was placed in the Trinity Chapel, which corresponded with the lady chapel in other buildings. That chapel henceforth became the goal of the pilgrims. It is recorded that while in one year a sum of nearly a thousand pounds was offered at BECKET'S shrine, not more than 4*l.* was offered elsewhere.

If we bear those facts in recollection the adaptation of the plan shows excellent judgment. It was necessary to set apart the choir for the use of the monks, and to preserve it as carefully as possible from disturbances. Accordingly we find that the entrance from the nave is as narrow as if the daily attacks of enemies were anticipated. The stalls were backed by screens of masonry, and, in fact, the central part of the church was jealously enclosed. Where were the crowds of pilgrims to go through their devotions when they could scarcely obtain a glimpse of the high altar? The plan suggests by the number of small apses that at one time there were more altars in Canterbury than in any of the other English cathedrals. Not only were they to be found in Trinity Chapel and the corona, but in the transepts, private chapels, and it may be along the nave. It is, indeed, difficult now to imagine the almost festive appearance which the interior of the cathedral presented when, as Dean STANLEY says, "bright colours on the roof, in the windows, on the monuments; hangings suspended from the rods which may still be seen running from pillar to pillar; chapels and altars and chantries intercepting the view, where now all is clear, must have rendered it so different that at first we should hardly recognise it to be the same building." A great many of the pilgrims would be fascinated by the multitude of wonderful objects, and it would be the aim of the authorities to encourage them in order to prevent the rush of a crowd to the Trinity Chapel. But the pilgrimage would be fruitless which did not comprise some prayers before the shrine. The approaches with their flights of steps were enough to check the advance of more than a limited number of people, and hence it is that although cripples and invalids daily visited the cathedral, there are no records of the sacrifice of the weak to the strong. Safety was insured by the arrangements of the architects.

Trinity Chapel was deprived of its principal treasure by HENRY VIII., but it is in excellent preservation, and apart from its historic interest—for it still contains the monument of the Black Prince—is worth reverent study from its architectural character and as the work of WILLIAM the Englishman. BRITTON was so enthusiastic in his admiration of it as to declare there was not a building in England or on the Continent that was worthy of comparison with it. Professor WILLIS is more sober in expressing its value, but what he says suggests the importance of the chapel:—

The Trinity Chapel of the Englishman is under the influence of the French work, of which it is a continuation, and accordingly the same mouldings are employed throughout, and the triforium and clerestory are continued at the same level; but the greater level of the pavement wholly alters the proportion of the piers to their arches, and gives a new and original and at the same time a very elegant character to this part of the church compared with the work of the Frenchman, of which at first sight it seems to be a mere continuation. The triforium also of the Trinity Chapel differs from that

of the choir, in that its four pointed arches instead of being, like them, included under two circular ones, are set in the form of an arcade of four arches of two orders of mouldings each. The mouldings are the same as in the choir, but the effect of their arrangement is richer. Also in the clerestory two windows are placed over each pier-arch, instead of the single window of the choir. The mixture of the two forms of arches is still carried on, for although the semicircular arch is banished from the triforium, it is adopted for the pier-arches. However, in the side aisles of the Trinity Chapel and in the corona our English William appears to have freed himself almost as completely from the shackles of imitation as was possible. In the side aisles the mouldings of the ribs still remain the same, but their management in connection with the side walls and the combination of their slender shafts with those of the twin lancet windows, here for the first time introduced into the building, is very happy. Slender shafts of marble are employed in profusion by William of Sens, and Gervase expressly includes them in his list of characteristic novelties. But here we find them either detached from the piers or combined with them in such a manner as to give a much greater lightness and elegance of effect than in the work of the previous architect. This lightness of style is carried still further in the corona, when the slender shafts are carried round the walls and made principal supports to the pier-arches, over which is placed a light triforium and a clerestory; and it must be remarked that all the arches in this part of the building are of a single order of mouldings instead of two orders, as in the pier-arches and triforium of the choir.

There is in one of the windows a sketch of BECKET'S shrine which stood in the Trinity Chapel, but only an elaborate painting could do justice to a work of art which ERASMUS described as "a coffin of gold, together with inestimable riches, gold being the meanest thing to be seen there; it shone all over and sparkled and glittered with jewels of the most rare and precious kinds, and of an extraordinary size, some of them being larger than a goose's egg." According to STOW, at the time of its seizure by THOMAS CROMWELL it was about a man's height, the lower part of stone, the upper part of timber. Within it was an iron chest containing the relics. The woodwork of the shrine was on the outside covered with plates of gold, damascened with gold wire. The gold ground was again covered with jewels of gold, such as rings which were fastened with gold wire, many of them having stones in them, besides brooches, images, angels, precious stones and great orient pearls. The spoil of the shrine in gold and precious stones filled two great chests, and it required six or seven men to carry one from the chapel.

The necessity to accommodate large but fluctuating crowds that were not always inspired by devotion alone was not without effect on those who took up the work of LANFRANC and ANSELM, of WILLIAM OF SENS and the English WILLIAM. They created a type of cathedral that might almost be called novel, one in which opportunities were given for the display of reverence not only to the Martyr but to other representatives of sanctity. Apparently the builders could not obtain the geometrical skill to lay out a long axis, for the plan shows there are deviations which are not to be explained by any theories of symbolism or optical effect. One flight of steps at least, with the king's screen or organ gallery, of A.D. 1304, can be credited to HENRY D'ESTRIA, who held the office of prior for nearly fifty years. The great transept was erected by Archbishop SUDBURY in 1379.

A more important work was the rebuilding of the nave and "Martyrdom" transept, under the direction of THOMAS CHILLENDE, of CHYLLINDENE, who was prior for over twenty years between 1390 and 1411. According to the custom of the time, an almost complete demolition of LANFRANC'S work was considered necessary, the plinth of the aisle walls alone remaining. It was about the same time that WILLIAM OF WYKEHAM, who was in his seventieth year, began the restoration of Winchester Cathedral. He was less thorough in dealing with the nave than was CHILLENDE at Canterbury, and yet, in spite of the economy which utilised a large part of the earlier work, he was able to produce a wonderful result, for, as Bishop LOWTH says, "There is no fabric of its kind in England, after those of York and Lincoln, which excels the nave and aisles of the cathedral church of Winchester in greatness, stateliness and majesty." As we have already suggested, it is difficult to determine precisely what share the WYKEHAMS and CHILLENDES of Mediæval times had in the pre-

paration of designs. It is remarkable, however, to find as much similarity between the nave of Winchester and Canterbury as if they were inspired by one artist or director. On this subject Professor WILLIS, in describing the Canterbury nave, writes :—

The style is a light Perpendicular, and the arrangement of the parts has a considerable resemblance to that of the nave of Winchester, although the latter is of a much bolder character. Winchester nave was going on at the same time with Canterbury nave, and a similar uncertainty exists about the exact commencement. In both, a Norman nave was to be transformed; but at Winchester the original piers were either clothed with new ashlar, or the old ashlar was wrought into new forms and mouldings where possible, while in Canterbury the piers were altogether rebuilt. Hence the piers of Winchester are much more massive. The side aisles of Canterbury are higher in proportion, the tracery of the side windows different, but those of the clerestory are almost identical in pattern, although they differ in the management of the mouldings. Both have "lierne" vaults, and in both the triforium is obtained by prolonging the clerestory windows downward and making panels of the lower lights, which panels have a plain opening cut through them, by which the triforium space communicates with the passage over the roof of the side aisles.

The nave being completed the external towers were next undertaken. But the most characteristic, called the "Central," "Bell Harry" and "Angel Tower," does not appear to have been commenced until 1472 by Prior SELLYNGE, and it was not completed until 1517, in the time of Prior GOLDSTONE II. The south-west tower was completed between 1449 and 1468. The cloisters are also fifteenth-century work, and to the same period belong the chapel of HENRY IV., Dean NEVIL'S Chapel and the chapel of the Virgin. The admired Christ Church Gate, "a goodly, strong and beautiful structure, and of excellent artifice," which forms an excellent finish for the view along Mercey Lane, and the south-western porch, date from about 1517. Examples of five centuries of building can therefore be found in Canterbury Cathedral, and as a rule what is seen is characteristic.

THE MUNICIPAL ELECTRICAL ASSOCIATION
MEETING IN MANCHESTER, 1897.

THE last week has been one of great interest to municipal engineers, as the second annual meeting of their electrical association has been held. The salient features of this association are that all directly interested in municipal electrical work are admitted to membership—electric-lighting committees, municipal electrical engineers, &c., in order that there may be complete accord and interchange of views on the subject. It must be said that the work is promising great success.

The Generation of Steam.—There are several very interesting papers on subjects of interest chiefly to central station engineers, but there are two which are of more general interest, referring to the subject of "The Generation of Steam," the authors being Mr. JOHN F. C. SNELL, Assoc.M.I.C.E., &c., (borough electrical engineer, Sunderland), and Mr. J. J. STEINITZ (borough electrical engineer, West Ham).

Taking Mr. SNELE's paper first, "The object of this paper is to bring before you the types of boilers in use and details connected with them."

Mr. SNELL gives several very interesting figures as to capital cost of the various types of boilers. These may be of interest.

Type.	Capital Cost Erected per 1,000 lbs. Max. Evap. per Hour.	Floor Space.
I. Lancashire { Without economiser	L76	69 square feet
" " With "	99	69 "
II. Water-tube	96	34'4 "
III. Dryback marine or "Economic"	94	34'4 "
IV. Marine	100	25 "

From these figures it would appear that the Lancashire boiler is the most expensive (with an economiser) and occupies the greatest space, and that with the rest the expense is greater, as the floor-space occupied is less.

The author states that the Lancashire boiler is very hard to beat, and the cost of upkeep is very low, while it can be

used with comparatively bad water. The defects of the boiler are admitted to be the length of time required to get a cold boiler under steam, the waste of water while warming up, and the collapse of flues due to want of care in cleaning and the effect of oil in the feed-water.

Mr. SNELL passes on to the water-tube boiler, and he says that the chief disadvantages are small steam space, wetness of steam, and cost of repairs and cleaning.

The life is given as being rather short (16 years), but the figures are qualified by the statement that "it only applies to the tubes, as the drum and headers should be as long lived as any Lancashire or other type of boiler."

We may say here that the wetness of steam is not a necessity with water-tube boilers. Any boiler is liable to give wet steam if forced too much, and the better types of water-tube boiler are very little worse than the Lancashire. The great advantage of these boilers, which is not sufficiently insisted upon in the paper, is their greater safety with higher pressures, and the fact that they need not be banked when not required. The cost of lighting up and getting steam again is less than the cost of coal and labour for banking a Lancashire boiler, if the time of waiting is anything like 24 hours. This quality is, we should think, very desirable with stations leaving low Sunday and Thursday loads, when several boilers have to wait 40 hours or more.

The "Economic" boiler is next mentioned, and is very properly described as combining the large steam room of a Lancashire boiler with the quick-steaming qualities of the water-tube. The repairs and necessity for good water are as great as with the water-tube boiler. The boiler has a great reputation for high efficiency, and is being largely used for electrical work. The life of this boiler is not given, but it would not be very high we should think.

The marine boiler is not spoken of very highly, and Mr. SNELL'S remarks may be compared with those of Mr. STEINITZ. "The author does not consider it so efficient as the 'Economic,' on account of the setting and arrangement of the flues. . . . The average life may be taken at eighteen years." Mr. STEINITZ says:—"The marine boiler has proved an unqualified success wherever it has been adopted. The average life would be rather less than the Lancashire boiler. . . . Many engineers hold that it is as important that the products of combustion in their course to the shaft should be brought into contact with all the heating surface as that there should be the good circulation of water. Should this be so, no boiler he is acquainted with fulfils the conditions better than one of the ordinary marine type." Mr. SNELL says with regard to circulation of water that this is insufficient in the Lancashire, "Economic" and marine

There is a slight mistake when Mr. SNELL says that "the cheapest and most useful battery of boilers will be found in the discreet combination of both types, as inaugurated by Mr. GAY at Islington." It is true that the combination was inaugurated by Mr. GAY, but it was not at Islington, but at the West Brompton station (House-to-House Company) some years before that he first arranged Lancashire and Babcock boilers side by side.

With Mr. SNELL'S remarks on feed-pumps, we cannot agree fully, and we think his comparison of the steam and electric pump is not fair to the former. The reasoning is not good. He says:—"It is well known that, at the average ratio of steam to drive the pumps to the feed-water pumped is some 3 per cent.," and then goes on to calculate on assumed figures the percentage of power to feed the boiler with electric pumps, and finds it 1 per cent. much more

It may be of interest here to give an extract from a paper read by Mr. W. FENNELL, A.I.E.E., before the students of the Institution of Electrical Engineers:—

Steam pump.—Uses, say 90 lbs. of steam per actual H.P. hour. Electric pump.—Steam in engine requiring 20 lbs. steam per E.H.P. hour, is converted into electricity with 75 per cent. efficiency, *i.e.* 26 lbs. of steam per E.H.P. hour (a lower figure than Mr. Snell's, which is 31 to 32); efficiency of motor, 75 per cent., *i.e.* 34 lbs. per H.P. hour, and as a motor is a fast-moving machine, and we *must* gear down very much, and the gearing is not efficient, say 60 per cent. efficiency between motor and water. Then we have nearly 60 lbs. of steam per actual H.P. hour with electric pump, as against 90 lbs. with a Worthington.

If Mr. SNELL'S figure of 31 lbs. of steam per E.H.P. hour is taken, the pumps are very equal. There must, however, be

a stand-by pump worked by steam, and the electric pumps are not so cheap as steam pumps, and more liable to break down.

Some actual figures would be very welcome on the actual results obtained from either kind of pump.

Mr. SNELL's remarks as to water-softening plant, and the fact that water should be softened before entering the boiler are to the point, and can be studied with good effect by all using boilers.

The good effects of heating feed-water, in preventing the sulphates of lime and magnesia from entering the boiler, being deposited in the heater and economiser tubes, are rather dubious, as they are as difficult to clean as a boiler. Surely, if Mr. SNELL can separate the oil from water in a condensing plant, as he says, he could do the same in a "mixture heater," *i.e.* one in which the exhaust-steam meets the cold feed and both are condensed; the greater portions of the salts are deposited immediately when water is heated suddenly, and the deposit acts as lagging to the heater and increases the efficiency.

We feel inclined to agree with Mr. SNELL on the question of mechanical stokers, which is that they are very good with small coal. It is questionable if small coal can be used with advantage in London apart from the smoke nuisance. As the carriage on the coal is a large proportion of the cost, and the carriage does not increase with the quality, it should pay to buy the good coal rather than slack, if dealing with the collieries almost direct, as must be done with large quantities. Of course, very cheap slack, the siftings and yard sweepings, may be obtained from coal merchants, but it is doubtful if this is worth burning in London at any price, owing to smoke troubles.

Near collieries, however, the small coal can be burnt with great advantage, and then mechanical stokers come in.

The author recommends section coverings for steam valves and the pipe flanges, and also recommends sluice valves, *i.e.* what are otherwise called slide valves, opening to the full bore of the pipe. An important point is mentioned in connection with long lengths of pipes, *viz.* the use of by-passes for warming-up and in the prevention of water-hammer. A table of tests on the various types of boilers are given, but the origin of the tests are not stated.

Turning to Mr. STEINITZ's paper, we are struck with the uncertain tone of the author. He writes, as it were, dubiously, and evidently has not made up his mind on many points. The types of boilers are not described, but a few of their peculiarities are discussed. For instance, he mentions that a well-known firm advised him not to have cross tubes fitted in the flues of Lancashire boilers. Bad circulation in these boilers is admitted, and the necessity of forced circulation is urged. A curious point is the maximum pressure at which a Lancashire boiler should be made. He says that a firm making a specialty of these boilers recommends tubular boilers for more than 120 lbs. per square inch.

Mr. STEINITZ thinks that the efficiency of the water-tube boiler is the highest ever obtained, but there is no doubt that many will disagree with him here. He agrees with our remarks on the question of banking, and answers Mr. SNELL on this point. The opinion of the author on the marine boiler has already been given.

Mr. SNELL and Mr. STEINITZ agree on the subject of suitable fuel, *viz.* that the best Welsh coal and ordinary hand-firing is best when far from a coal-field.

On the subject of boiler compositions the author says:—"Boiler compositions may be good; they may also do more damage to the boilers than good to the water, but whatever is done to the water, the author's point is that it should be done outside the boiler." In this matter again we agree with him to a great extent, but there are cases where a little good boiler composition is a help. For instance, when the greater part of the carbonates, &c., are deposited in the heater there is always a certain amount of deposit in the boiler, and this must be got rid of.

With regard to oil in feed-water, the author gives a very practical suggestion in this connection, and one which may be of special use to engineers working with condensing plant. He says, "A coke filter used intelligently will be found to be all that is required," referring to the means of keeping the cylinder oil from the boiler-feed.

The use of mechanical stokers is next entered into very fully and ably, but as the subject is of interest to few but

electrical engineers, it will be advisable to do little more than mention them.

The author's experience is that a mechanical stoker which sprinkles the coal on the grate is to be preferred for central stations, because the boilers can be forced more easily than with a coking stoker (one which pushes the coal on at the front and feeds it back).

The remaining point of general interest is the use of economisers. The author says that he thinks there is one installed in almost every central station in the kingdom. This surely is hardly correct, because he says later that where the temperature of the flue gases is below 400 deg. Fahr. they are useless. This lower temperature is very usual with a good water-tube boiler.

The liability to corrosion of the tubes is touched upon, and the remedy of heating the feed slightly before it goes to the economisers is, of course, suggested. The use of forced draught, either by steam jets or fans, is mentioned as saving capital outlay by reducing the number of boilers in cases where the maximum load is on for a short time only, as the boilers can be forced very greatly, and also for burning poor qualities of fuel.

We think that the plan of closing the stokehole and of forcing air into it, the only outlets being through the furnaces, which system is used at sea, and which the author suggests for land purposes, will hardly be adopted. The inconveniences of such an arrangement would be too apparent.

In conclusion, these papers raise many interesting points, which should bring out an interesting discussion.

PRODUCTION OF STATUARY.

THE first thing to settle in a statue or group is the general design. For this purpose the artist, having chosen his subject, makes one or more sketches on paper, representing his conception of the treatment appropriate to it; these he will vary as improvements on the original idea suggest themselves, or as new notions spring up. Having to a certain extent satisfied himself with one or other of them, as expressing fully what he wishes, and as being at the same time harmonious in its arrangement, he then proceeds to make from it a small sketch or model in clay, in order to ascertain its probable effect in other views than the one represented on the paper. For it must be recollected that sculpture is widely different from its sister art, painting; the former has many views to consider, the latter has but one; and though in a piece of sculpture there will of course be principal views more effective than others, still they must all be agreeable, and to a certain extent suggestive or expressive of the main idea; and for this reason the sculptor has frequently to sacrifice or modify that which, were only one view to be considered, would aid him forcibly in his intentions. It is scarcely necessary to say, therefore, that alterations occur again in these clay sketches, and more than one is frequently made before the final decision on the question of design takes place. This done, the full size model is commenced in clay, the same material as the sketch, and for this the artist has to supply supports, as it rarely happens, except in recumbent figures, that the clay will hold itself together in the required position without their aid; no difficulty exists, however, in providing these, the roughest hedge-carpentering answering the purpose better than the finest workmanship. All that has to be done is to build up upon the stool a rough woodwork of sufficient strength to bear the weight of the clay and prevent it sinking, and to so arrange it that it shall be contained within the surface of the proposed model. Upon this the clay is kneaded by the hand into the requisite form, unassisted by anything but a few very simple wooden tools that help to cut, scrape or press, as may be required. The clay itself is that prepared by the potters for the common white stoneware, and is in no way expensive. Young inexperienced artists often show an over-strong predilection for the use of these wooden spatulas, or modelling tools, as by their assistance they find they can more easily obtain a smooth surface to their work; but experience afterwards teaches them that an imitation of the pulpy surface of the flesh can only be obtained from the touch of flesh itself, or, in other words, from the pressure of the finger and thumb, and that the wooden tools must be used sparingly, merely as assistants to the hand, otherwise a hard mechanical style is apt to creep in. There is in truth in a real artist, when working on his clay, the same species of feeling as in a fine pianoforte player, who draws expression from the instrument, not barely from correctness of note, but from a mental absorption in the music which imparts itself to his touch, and this affinity between head and hand is interrupted in the sculptor when the modelling tool intervenes between the surface of his work and the delicate sensation with which his hands are endowed.

With persons unacquainted with sculpture there is a general impression that the cutting of the marble is the most difficult part; but those who are intimate with the art know that the designing and modelling are the primary portions, and that the other, though of course requiring some knowledge as well as taste, is, in comparison, scarcely more than a clever manual dexterity. The artist, in fact, employs his own hand almost entirely on the designs and modelling, for in these stages he has to originate almost all the beauties of his work, and he knows if his model be in any way defective, inaccurate in its proportions or wanting in beauty or expression, that there is no hope that such defects will be remedied in the marble. The latter portion is indeed, in a measure, a mechanical process of copying, restricted, by the very means it employs, from departing to any great extent from the model. Before the model is finished nature must be referred to, and that frequently, to give an air of truth to the figure, which never was and never will be gained except by reference to her. We will, however, suppose that the sculptor has by dint of time and labour thoroughly studied his model, compared it with and corrected it from nature, arranged his draperies and subordinate parts in proper order, brought all the surfaces up to a necessary degree of smoothness, in fact, given to the best of his talent and power actual embodiment of that which his mind has conceived. It is still in the soft clay, which will not bear moving, nor be durable for long, as it is liable to shrinking, and, if not constantly supplied with moisture would eventually crack, owing to the supports within not allowing every part to diminish in an equal degree. It has for this reason to be moulded and cast into plaster, a process we shall briefly describe. Plaster of Paris is a strong, fine, white lime, made from gypsum or alabaster ground to powder and baked; and, so prepared, has the property of crystallising rapidly when mixed with water, or, in other words, of condensing itself into a hard body. A certain quantity is mixed with water, sufficient to form a liquid of about the consistency of good cream, and thrown over a portion of the model, walls of soft clay having been built round that portion in order to prevent it from running on the other parts. The object of thus covering a part only at a time will be seen presently, and the proper division of such parts must be learnt by experience, as it depends entirely upon the peculiarities of the model. This liquid plaster of Paris will, under the hands of an experienced workman, take an exact impression of the surface, and in the course of a few minutes become hard, as we have before explained. More must be added, however, in order to render it of the thickness necessary to sustain itself, which thickness will depend on the size of the object to be moulded. The clay walls are then removed, when we have one-half or more of the model covered with a hard shell, the edges of which stand up clean and square from the clay. These edges are then soiled with clay water, and the same process goes on with the other half; or, if it be a very complicated work, there may perhaps be three, four, or even five pieces of mould, all made in this way in succession.

The whole having been covered, after this manner, with a coating, the inner surface of which has taken a delicate impression of every marking on the model, the next step is to open this shell or mould, in order to take out the clay. If the joints between the pieces have been well washed with clay water, these will separate easily by the driving in, at judicious distances, a few wooden wedges. At any rate, one piece will come away by this means, and from the opening thus made we can pick out the clay, just as it will best come, only taking care not to injure the surface of the mould, as any damage done to that will show itself in the cast. The interior of the mould is now washed with a soft brush and water, and the pieces again put together and bound round with ropes to keep them to their places. The whole is well saturated with water, and fresh plaster of Paris of a finer quality poured into it through the mouth formed by the underneath side of the base. This also, becoming in a few minutes hard, forms a facsimile in plaster of the clay model, to be afterwards extracted from the outer casing or mould. Between the surfaces of the two, however, there is but little adhesion, as the saturating the first with water previous to filling it with the second prevents it. The removing the outer coating is accomplished by chipping it off in small pieces by means of a mallet and blunt chisel. This part of the work requires considerable practice as well as caution to prevent injuring the cast; but if everything has been well managed the pieces will splinter off before the edge of the chisel reaches it. To remedy at last any little faults or inaccuracies that may have occurred, rasps, glass-paper, fish-skin and for small work Dutch-rush are used.

The working of the marble now begins which, if it require not the highest talent, takes at least the longest time and the greatest labour. The model and marble are fastened in relative positions on two square blocks of stone, having each, along the edge in front, a scale of parts marked out, similar to those on a carpenter's rule. The "pointing instrument," as it is called, is then applied, which consists generally of an upright pole, with a cross-piece attached, that travels along the edge so

marked, just as a T-square travels along the edge of a drawing-board. (This pointing-instrument may indeed be well conceived by fancying a large T-square, the long part round instead of flat, and perpendicular instead of horizontal.) To this is attached a circular metal bar, and at the end of that again a needle, with ball and socket joints between both. By the aid of these joints the workman can fix the point of the needle to any part of his model, and having by means of the screws tightened the joints, can transfer the instrument from the stone on which the model rests to the other, when of course the relative position of that part in the marble will be indicated if the instrument itself be fixed to the corresponding number on the scale. It is, in fact, nothing more than a system of finding a third point from two already given. Various improvements have from time to time been made on this instrument in order to gain facility of motion, but the principle in all is the same. The best one is, perhaps, that invented by Behnes, for which the Society of Arts awarded its gold medal. It possesses greater variety of movement than any other, and, as such, is more convenient to the workman, but has one drawback—a too great liability to get out of repair. Indeed it will be easily understood that in an operation where dust and small pieces of marble are constantly flying about, it is not advisable to have to do with machinery of too delicate a construction. By this simple method the block is hewn out roughly, but correctly, into shape, and a great number of points or perforations are made in it, the bottom of which represent the surface of the model, and correspond in distance from each other with small pencil dots, marked at the time of taking them upon the model. These marks on marble and model form so many guides for the carver who now takes the work in hand, so that his mind is entirely relieved from the apprehension of any error in the main proportions or position of parts, these being definitely fixed by the points themselves. He has merely to copy what he sees correctly, by the aid of those points, and to bring the whole to a good fine surface; his ingenuity is displayed in clearing out with his chisel and hand-drill the deep cuttings—often a very difficult task, attended not only with a great deal of labour, but requiring considerable skill as well as practice. The marble comes at last again into the artist's studio, from whence the model emanated; and his delight is then in giving those final touches which remove from it any hardness or immobility it may have acquired under the hands of a copier, and impart to it the spirit and character of nature. The whole is ultimately rubbed over with sand and water by the aid of small pieces of wood and linen rags, to remove the dry, dusty appearance derived from the chisel or rasp, and to bring up the lucid beauty of the material.

When the multiplying of casts is required, as is frequently the case, a mould is again made upon the finished marble, much after the fashion previously described with the clay, but composed of an immense number of pieces, fitting one within the other, so as to admit of each one coming away separately from the marble, and, again, from the casts, without injury to either. This is professionally termed "safe moulding," on account of the outer coating being preserved; in opposition to the other, which is called "waste moulding," from the shell or mould being destroyed in the process. Any reasonable number of casts may be taken from the safe-moulds.

Bronze casting is another distinct process, little understood by artists themselves, and requiring, moreover, considerable accommodation in the way of premises, furnaces, apparatus, &c. For these reasons it is frequently entrusted to regular trade founders, who understand well enough the moulding and melting of metals, but who cannot be expected to comprehend the niceties required in a good work of art. The consequence is, in this country at least, that considerable deterioration often takes place, the bronze casting representing but imperfectly the form of the original model. The practice in these ordinary foundries is to mould the parts of a statue in sand and loam, after the manner of common metal castings, and without doubt much expense is thereby saved; but the result is never quite satisfactory, as these materials are not fine enough to take a sharp impression, nor stable enough to retain it uninjured during the operation of building the core and pouring the metal, owing to which many parts of the mould have to be repaired by the workman, and accuracy to the model is lost. In engineer's work castings are all afterwards made true by planing, turning, filing, &c.; so that, provided they be sound, it is not positively necessary that they should be in every respect accurate. Not so with fine art bronzes. Chasing—in fact, all tool-work on the metal—tends to destroy freedom of manipulation, and to produce in its stead a stiff, mechanical style, the reverse of all semblance to flexibility. It is desirable, therefore, that a bronze statue should be cast from the mould as perfect as can be, and that it be subject as little as possible to the operation of the chaser's chisels and punches, though of course these must be brought into use, to a certain extent, as matters of necessity rather than choice.

Moulding for bronze requires frequently that the plaster model should be cut into parts; it rarely happens in fact that a

statue or group can be cast in one piece, owing to difficulties that arise, first from the moulding itself, and secondly from the running of the metal into that mould. It will not be requisite to describe the moulding of these pieces, as the process is similar to that previously performed on the clay, with some modifications necessary to suit the nature of metals. There are, however, two or three points which require especial care and attention, and which regulate many of the contrivances adopted in it, and by alluding to these we shall at once enable the reader, aided by what has already been said, to understand the whole business. One of them is the necessity for fully providing for the free entrance of the liquid metal into the mould, as well as for the easy and perfect escape of the air out of it, as it becomes displaced by the metal; for without proper arrangement for this there is not the slightest chance of the cast being sound, and explosions may take place, destructive not only of the work, but even of life itself. For this reason channels have to be made in the joints of the mould down which the metal is first made to run, whence, entering the vacancy left to form the cast at the lowest point, it rises upwards through all the parts and the air can thus easily escape through other channels cut for that purpose. It should be here mentioned for the benefit of those unacquainted with the nature of metal casting, that there must always be provided an inner mould, or as it is termed, a core, to regulate the thickness of the metal. This is managed by laying on the surface of the outer mould clay of the required thickness, and then filling up the interior with the same material as the mould itself, after which the outer mould is removed and the clay taken away, leaving the necessary vacancy for the metal between the two when they are again put together. The material to form the mould and core must be of a consistency to retain the impression given to it from the model, of a nature to resist the action of the hot metal and sufficiently porous to allow the escape of gas, without which the liquid fire will not settle quietly and soundly down on its surface. Sand moulds act well as far as the last two are concerned, but are too fragile for the complicated forms of statue moulding, and experience has taught us that a mixture in equal proportions of plaster of Paris and brickdust serves best all purposes, the former giving it consistency and the latter answering all desiderata with regard to the metal. These brickdust and plaster moulds are of course tender, and must therefore be duly supported with irons embedded within them, as well as built upon iron basements, to enable them to be lifted about without injury by means of cranes. When complete they are bound round by iron hoops, and put into an oven to dry for five or six weeks, according to their size. Care in this particular is highly important, as the least damp will cause a bubbling or disturbance of the metal as it runs in. At the end of this time, when the casting takes place, the mould is lowered into a pit prepared for the purpose, and tightly embedded in sand; weights are put upon the top to prevent the uprising of any part as the metal enters; every precaution, in fact, taken against expansion. Channels are then made of sand from the orifice of the furnace to the mouth of the mould; the furnace is tapped, and the liquid flame rushes out through the roads so formed for it. This is the anxious moment upon which the result of many weeks' work depends. If the metal run quietly down the mould, and appear again up the passages formed for the escape of the air, it is but reasonable to infer that it has travelled through every part, and that a good cast will be the result; but if by chance a beautiful *jet-de-feu* takes place, reaching almost to the foundry roof, it may be as well to retire to a respectful distance, notwithstanding that the dispersion of so much valuable metal may create a desire to see where it falls. The moulder, too, may recommence his work immediately, for waiting until to-morrow, when the mould and cast are to be dug out of the pit, will be scarcely worth while. No bronze-mould can serve for more than once, and the cast will be found to have a strong resemblance to a honeycomb, very curious, no doubt, but not exactly suited to display clear definition of form. Such noisy and expensive fireworks do not, however, take place in a well-managed affair, where there is everything proper for use and every care taken; but the mention of them may serve to caution those who have not the means at hand to do what is right, or who meddle with the process without the necessary knowledge or experience to guide them. Some variety of opinion exists on the question of what this metal called bronze should be composed; but the late Mr. Maudsley, no mean authority, declared ninety-one of copper to nine of tin to be the best mixture for figure-casting, and his opinion has certainly been found correct. An addition of about one and a half of zinc, put in when the copper is melted, makes it flow more freely; but a greater quantity than this is scarcely justifiable, as zinc is liable to be acted upon by acids, and, if used too freely, may endanger the durability of the statue. The mould comes off from the cast in dry dust, as does also the core from the inside. The parts called runners, formed on the cast by the metal filling up the passages through which it has flowed, and the projecting lines, caused by the seams or

joints, have then to be cut off, and any little defects remedied by the chasing-tools. The whole should then be scrubbed with emery and water to remove a green scurf attached to it, the presence of which is, however, a sure indication of a good surface beneath. The last proceeding is to join the various parts so cast. This is done by first fastening them together by bolts, and then pouring hot metal from a crucible over the joint; 6 or 7 inches at a time, when embedded in sand so as to expose nothing but the edges required to be united. When cool, this leaves a piece of metal standing up, to be afterwards cut away. A repetition of this operation, all along the joint, will be found to unite the parts as solidly as if cast at one time, and will not be at all visible in the finished work. The statue is then complete. Attempts, it is true, are sometimes made to give an artificial colour to the metal, by means of acids, before it leaves the foundry; but time does that better than anything else.

THE AUGUSTINE CELEBRATION.

ON Friday last the bishops attending the Lambeth Conference visited Ebbs Fleet and Richborough. In 1884 Lord Granville erected a copy of the Sandbach Cross to mark the spot where the Roman missionary is supposed to have landed. Richborough Castle was afterwards visited, when the following address was delivered by Canon Routledge:—

In welcoming you to Richborough, on behalf of the trustees, I cannot forget that it is mainly owing to the devotion and liberality of two persons that this historic castle and grounds have been preserved for ever to the Church of England and the nation. One of them has passed to his rest, to our unfeigned sorrow; but we shall never forget the keen interest which Archbishop Benson (antiquarian, scholar, ecclesiastic) showed on all occasions in the acquisition and maintenance of Richborough, nor the wise judgment and extensive knowledge with which he organised so many details of the solemn functions that we celebrate in this Augustinian pilgrimage. The other is still with us this afternoon, and what we owe to the princely munificence and unremitting zeal of Lord Ashcombe is well known to the trustees, and is only not known to the world because of his unostentatious character. None the less do we thank him, and regret that for private reasons he has felt himself compelled to resign his office as trustee.

Now the interest attaching to Richborough Castle is twofold. In the first place, it is one of the grandest monuments existing in England of the Roman occupation. As a fortress and a harbour Rutupiae finds frequent mention in Roman writers—Lucan, Juvenal, Ptolemy, Antoninus, and others—and down to the beginning of the fifth century was the headquarters of a Roman legion. Probably the last Roman soldiers that were ever stationed in Britain embarked here at the close of their occupation, and it was only a few years ago that a beautiful gold coin of the Emperor Honorius was discovered not far from the spot where we are now standing.

The second interest—the one perhaps that most appeals to this distinguished assembly—is ecclesiastical. That learned book lately compiled and written by Canon Mason, "The Mission of St. Augustine," claims for Richborough more perhaps than all antiquarians are disposed to concede, viz. that it was the landing-place of Augustine and his companions, to the disestablishment and disendowment of Ebbs Fleet. And this belief is supported by testimony that reaches back for five or six centuries in the narrative of Thorn, a monk of St. Augustine's Monastery at Canterbury. It is certain, too, that up to the time of the Reformation there was a chapel here, where of old was perceived a stone that was said to retain the print of St. Augustine's foot as he left the ship. And this chapel is mentioned in the will of Prebendary Saunderson, vicar of Ash. What amount of truth is to be attached to this ancient tradition, or to another stating that St. Augustine was received under these walls by Ethelbert, King of Kent, it is not my purpose to discuss on the present occasion. But on one point we are all agreed; even if St. Augustine did not actually land at Richborough, but disembarked near Ebbs Fleet, it is almost certain that he would have crossed over from Thanet to the island of Richborough, and thence started on his pilgrimage by the western Roman road, through Ash and Wingham, to Canterbury.

Looking at the present formation of the ground, with the coast line more than two miles from the eastern side of the fortress, it seems almost drawing on your credulity to assert that it was once washed by the open sea. But so it was, guarding the southern entrance of the Wantsum Strait, while the northern entrance was commanded by Regulbium or Reculver. This strait was the most direct way into the estuary of the Thames for vessels sailing (as St. Augustine's did) from Gessoriacum, or Boulogne.

Just below the south-eastern side of the fortress was a narrow stretch of sandy shore, where (on the construction of the Ramsgate and Deal Railway in 1846) were discovered the foundations of a Roman house, and at no great distance many

refuse-pits were found filled with portions of stags' horns, animal bones and pottery—a sure sign of dwellings in the vicinity.

A detailed account of the fortress may be found in the descriptions of Mr. Boys (1792), Mr. Roach Smith (1850), Mr. G. Dowker (1871), Mr. G. E. Fox (1896), and of other writers, so that it is only necessary for me to enumerate a few of the more important particulars.

The camp is a regular parallelogram, with the greatest length from east to west, containing within its walls an area of between 5 and 6 acres. The walls (of which you noticed a splendid specimen in your procession from the railway crossing) are built of a core of concrete, cemented with sea-shore mortar, the external facings being of regular courses of squared grit and Portland stone, with binding courses of Roman tiles. In some places the walls are nearly 30 feet high and 10 feet 8 inches wide. These walls are now visible only on the north, south and west, but it is more than probable that there was also an eastern wall at the foot of yonder slope. At each corner of the camp was a large circular bastion, while two square rectangular tower-bastions projected from each wall, of which traces are still evident in the west and north. These afforded platforms on which military engines could be placed. The only remaining gate is the postern by which we entered, but from foundations laid bare in 1792 we conclude that the "Porta Decumana" existed in the west wall, now the ordinary entrance to the castle grounds.

The great subterranean structure over which we are now standing measures 124 feet by 80 feet below the surface; and 144 feet by 104 feet on the ground level. It has been partially explored over and over again, and was long considered to have enclosed a large chamber or storehouse for the Roman soldiers. But, beyond all reasonable question, it is a solid mass, probably of earlier date than the external walls of the camp, intended as a foundation for some large and important superstructure.

On the centre of this platform, just within these hurdles and of a later Roman period than the solid mass beneath, is the cross of masonry (commonly called St. Augustine's Cross), measuring from north to south 87 feet by 7 feet 6 inches, and from east to west 22 feet by 47 feet. It was a happy thought of that eminent and genial archaeologist, Mr. T. Godfrey-Faussett, that this cross was the foundation of a solid stone wall that formed a kind of internal support to a timber Pharos built around it, being at once a lighthouse to guide ships into the haven and a signal tower to communicate to Reculver (at the other end of the strait) the tidings of the approach of an enemy.

And so (in conclusion) we once more bid you welcome to this classic spot, famous for its antiquarian and ecclesiastical interest, a mine of treasures and relics in the past—and destined in the future (through, I hope, the liberality of some who hear me) to be a mine of archaeological discoveries.

When many of the bishops return to their distant homes in the colonies and the United States of America, they will (let us trust) keep one corner of their hearts for the memory of Richborough Castle, associated with Ebbs Fleet, and St. Martin's Church, and the ruins of St. Pancras, and the great and crowning glory of Canterbury Cathedral.

NON-FLAMMABLE WOOD.

A PAPER on non-flammable wood was read by Mr. C. E. Ellis at the International Congress of Naval Architects on Tuesday. He said that as long ago as 1625 a patent was granted by the English Patent Office to one Beale for "a dressing for shippes and other vessels as their mastes, deckes, tackles, sayles and other furnitures, that they maie be preserved in fight at sea from burning or consuming by wildefeyer or gunpowder." From that period forward countless efforts had been made to obtain the desired result, but no plan seemed to have been devised for securing what was absolutely essential, namely, that the fire-resisting treatment should permeate the heart of the wood so as to render it internally as well as externally fireproof. It was obvious that the main difficulty of getting rid of the combustible elements and substituting others lay in providing means for treating the cells without rupturing their delicate structure, and so deteriorating the value of the timber. It was claimed for the new non-flammable wood that this difficulty had been successfully overcome. By this process the timber was placed in a cylinder and a vacuum formed. Steam was then admitted, causing the moisture in the wood to vaporise, the products of the vapour being drawn off. A vacuum was again formed, and the saturating liquid, containing certain salts, was forced in fine spray mixed with steam into the cylinder until the wood was thoroughly impregnated. The wood was then dried and ready for use. The salts which were thus forced into the wood by the process of saturation retarded the rapid

carbonisation of the wood under high heat, and particularly the generation of combustible gases, which were the cause of flame. That wood so treated was incapable of supporting or conveying flame was conclusively proved at special experiments. Two buildings were erected similar in design, one being built of ordinary and the other of treated wood. They were about 11 feet square, with the floors about 4 feet from the ground, the lower portions of the walls below the floor being formed of open trelliswork, so as to allow for circulation of air and flame. The height of the buildings was about 30 feet from the ground to the top of the wooden chimney. The framework and walls were constructed of pine internally fitted with linings of ash, oak, birch and mahogany. Equal quantities of dry wood saturated with petroleum were piled to windward of each building and simultaneously ignited. The untreated building was ablaze in a few minutes, and in half an hour was completely destroyed. The treated building, on the other hand, showed no signs of burning, except where the trelliswork and walls were charred by actual contact with the flames from the burning firewood. On entering the building at this stage it was found to be quite cool inside, both on its walls and floor. A further test was then made of the treated building by igniting a large heap of shavings and firewood inside the structure. By means of open doors and windows and the high open chimney-shaft, a strong draught was created. The flames from the burning wood rushed up through the chimney, melting the glass in the windows, the fire burning furiously for about twenty minutes. On entering the building it was found that it had been charred, as in the previous experiment, but that structurally it was quite uninjured. A box made of treated wood which had been inside the house during the fire was also found externally charred, but its contents remained in perfect condition. The success of the experiment upon the wood was apparent to all who witnessed it. Similar trials had been made in the United States, but the details did not differ from the London experiment.

BERKS ARCHÆOLOGICAL SOCIETY.

AN afternoon meeting of this Society was held in the Abbey Gate, Reading, on the 1st inst., under the chairmanship of Mr. Charles Smith, vice-president, and was attended by the Rev. J. M. Guilding (hon. treasurer), the Rev. P. H. Ditchfield (hon. secretary), the Revs. Alan Cheales, T. Flook and J. J. Goadby, Mrs. C. Smith and Miss Smith, Miss Pigott, the Misses Jackson, Mrs. Suffield, Miss Dowsett, Miss Righton, Miss Bird, Miss Strong, Miss Williams, Mr. W. M. Childs, Miss Pollard, Mrs. Ryan, Mr. Ernest Wright (assistant secretary), &c. Formal business having been transacted, the Chairman said that, the Queen being their patron, it was thought desirable that the Society should send an address to Her Majesty, and called on Mr. Ditchfield to read the draft which he had prepared, inviting criticism.

The Rev. P. H. Ditchfield read the address, and moved a resolution to the effect that it be suitably engrossed, signed by the President, and forwarded to the Queen.

The Rev. A. Cheales seconded the resolution, which, after a few words from the Chairman in support, was carried unanimously.

STAINED-GLASS WINDOWS.

THE choice of subject for the windows of a church must always depend on the nature of the design, and the nature of the design that ought to be adopted will be found to vary much with circumstances. In some buildings a window, from its distant situation, would be more effectively filled with a mere pattern than adorned with a picture in glass. The great object to be borne in mind is the general effect sought to be produced. Every window ought to contribute to the effect of the whole building, and therefore ought to be designed with reference to its situation. If a picture glass painting, it ought to tell its story distinctly at that distance from which a spectator would view it, as forming part of one general design. Nothing, as it seems, is more erroneous than to extol an Early English medallion window because, when seen from a distance, it resembles a mere pattern window in effect; for, seen from this point, the more elaborate workmanship of the figures in it, as well as the greater cost of the work, are thrown away, and in effect it is inferior to a pattern window, because a more exact balance and arrangement of colour can be preserved in a mosaic consisting of a stiff formal pattern than in one composed in great part of figures and draperies.

M. Falguière has set up in the Panthéon, Paris, his colossal group *The Revolution*, which recalls a figure of Joan of Arc with another woman dragging her back by the gown.

NOTES AND COMMENTS.

THE parliamentary committee on the Science and Art Department have already presented a memorial to the Treasury describing the dangerous condition of the South Kensington Museum. The decision on the subject has to be announced, but meanwhile additional evidence is being given. On Monday Sir JOHN TAYLOR, the chief surveyor of the Office of Works, described some of the structures at South Kensington as being of an extremely inflammable character. There were also, he said, old and dilapidated buildings used for residences and offices. Sir JOHN TAYLOR considered that the whole of the temporary buildings should be removed as rapidly as possible. It was impossible, he said, to make them safe. The wisest course would be to pull them down and to erect suitable buildings. Sir JOHN TAYLOR recommended the rebuilding of the museum as a whole, which could be accomplished in about five years, and during the rebuilding a part of the treasures could be placed in the Tait Gallery at Millbank. Sir JOHN explained that the designs for the new buildings had been selected five years ago and some of the working drawings were ready, all that was needed was money. It is not often a surveyor of the Office of Works is found to be so emphatic in his condemnation of buildings which belong to the Government, but without plain speaking it is to be feared the parliamentary session will be closed and the rebuilding indefinitely postponed.

ALTHOUGH Paris possesses institutions which are known as cercles or clubs, where pictures can be exhibited and social functions be gone through, the artists do not possess a club in the English sense of the word. The cafés and restaurants on the boulevards have served as substitutes, but their number is declining, and those which were select are being closed. In 1900, when so many foreign artists are likely to visit Paris, it will appear inhospitable if they cannot be entertained occasionally in some building which French artists can claim as their own. It is therefore proposed to found a club which can be used as a place of reunion, and where foreign artists could have a footing as honorary members. M. BONNAT, the portrait painter, has taken up the project, and already he has secured the co-operation of several painters as well as of architects and sculptors. He is sure to attain further success, for the club will be formed, and it will be additional evidence of the desire by Frenchmen to possess English institutions, or imitations of them, at any cost.

THE demolition of the Palais de l'Industrie in the Champs Elysées has caused a novel revelation of Salon exhibitions. It will hardly be credited that every year there are paintings and models of statuary which the creators do not care to claim after the close of the season. From year to year they have been accumulating, and at present there are about 150 pictures and 50 examples of sculpture, besides works of art in other forms, among the castaways. The secretary of the Société des Beaux Arts has appealed to the artists to remove their property, but very few of them have responded. The majority are indifferent to the fate of the works of their hands. But as the building had to be cleared, it was at last decided by the committee to remove the pictures and plasters to one of the big pantechnicons of Paris, where they will be sheltered for a time. It is difficult to discover all the reasons which have inspired so much neglect. It is understood, however, that in most cases there are liens on the works. A picture or bust is not a sacred object to a bailiff, and he is not afraid to affix a seal in the principal division of the Salon. But when the law has asserted its jurisdiction the artist does not care to give facilities for the disposal of his productions by the Court, and through divided interests they at last become a burden to the authorities of the Salon.

THE Morris columns in Paris were inspired by a happy thought, for by means of them, advertisements and bill-sticking are brought under some control. Theatre-goers

find them a convenience, for the announcements are brought together within a limited space. But M. MORRIS is not allowed to enjoy his invention gratuitously. Every term he has to pay a higher sum for the concession. This year the increase has gone beyond anticipation. The rent for the period just expired was 14,000 francs. After long negotiations M. MORRIS has had to agree that he will pay no less than 80,000 francs annually for a renewed term of nine years, and to that arrangement the Municipal Council agreed a few days ago. The lessee will have the advantage of the exhibition year, but it is unlikely that at the end of nine years there will be a reduction. The Municipal Council, like the hotelkeepers and the restaurateurs, have surprising tenacity for prices which are supposed to be adapted to occasional circumstances.

MR. JOHN BURNET is one of the seniors of the architectural profession in Scotland. His experience has been most varied, and in Glasgow and the western district of Scotland there are many buildings which are memorials of his skill in meeting ecclesiastical, domestic and commercial requirements. Of late years Mr. BURNET has been ably aided by his partners, viz. his son, Mr. J. J. BURNET, and Mr. CAMPBELL, and he is able to retire from the more active duties of his position with the consciousness that the business will continue to be worthily conducted. On Monday several of Mr. BURNET's friends presented him with his portrait as a memorial of their esteem. It was painted by Mr. JAMES GUTHRIE. Mr. W. GILFILLAN, in offering the gift, said that at the end of 1895 Mr. BURNET celebrated his golden wedding, and that period happened also to coincide with his jubilee as an architect. Many of his friends thought that such an occasion should not be allowed to pass without something being done to mark so unique a combination of circumstances. The feelings of his professional friends were as warm for him in his retirement as they had been in the heyday of his career. Mr. BURNET, in the course of his reply, gave some interesting reminiscences of his early days as an architect, and referred to the influences that had given shape to his professional work. He thought that some training in one of the trades with which architecture had to deal was of great value to the architect. Doubtless architecture might be more quickly taught in a technical college, but the knowledge so gained was apt to be superficial. He was proud of their handsome gift, and he was especially grateful for it, because of the kind feelings that had prompted it. Everyone who has met Mr. BURNET will share in the feeling that he may long enjoy those desirable accompaniments of such an age as he has attained, viz. "honour, love, obedience, troops of friends."

ILLUSTRATIONS.

CATHEDRAL SERIES.—CANTERBURY: CLOISTERS, LOOKING SOUTH-EAST, AND PART OF TOWER.

THE illustration shows the lower part of the central tower which imparts so much dignity to the cathedral. The large window belongs to the chapter-house and the transept window to the "Martyrdom." Although there is less variety in the cloister openings than is seen in some other examples, the arrangement is excellent.

CANTERBURY CATHEDRAL.—NORTH CHOIR AISLE, LOOK'NG WEST.

ONE of the most picturesque aspects of the interior of Canterbury Cathedral is presented from the spot shown. The more ancient tomb is Archbishop CHICHELE's and the design was evidently arranged by that prelate, who wished to suggest that he knew he was not exempt from the fate of ordinary mortals and was doomed to arrive at the condition of the lower reclining figure.

The second tomb is Archbishop HOWLEY'S. His name was often to the fore during the Jubilee celebration, for he officiated at the coronation and marriage of Her Majesty the QUEEN.

THE ARUNDEL TOWER, CANTERBURY.

THE general view of Canterbury Cathedral which we published last week, comprised, among other features, the two western towers. They appear alike. If compared with any of the views which appeared in the first quarter of the present century a great difference will be observed. In the older views the north-west tower does not rise to the same height as its companion, and it might be imagined that some rule prevailed in Mediæval times like that which was observed at a much later period in the church of St. Sulpice, Paris, which prohibited uniformity. Whatever was the cause which made Lanfranc's or the Arundel Tower at Canterbury inferior to its companion cannot now be determined, for the structure succumbed nearly seventy years ago. The lower storey formed a complex vault which attracted the attention of Professor Willis, and when the stones were deposited in the nave of the cathedral he found the surfaces of the spandrel stones covered by lines and profiles of mouldings similar to those discovered at St. Saviour's, Southwark, thus proving that the same method of laying out work continued in use from the period of its first introduction.

An elaborate description of the Arundel Tower was published by John Carter, the architect, in 1833, and is now worth reprinting:—

The north-west tower of Canterbury Cathedral, lately destroyed, was known as Lanfranc's Tower, but was not built till upwards of seventy years after the death of that prelate. This magnificent relic of Norman architecture had seven conignations between the ground and the summit, and as many stages, and was 119 feet 9 inches high. The platform or base on which it stood was of enormous bulk and strength, and originally measured full 36 feet on every side. The area of the tower was a trapezium. The east and the west sides were parallel, and measured respectively 18'4 and 19'2 feet. It should be remarked that a line was drawn through the centre, and the excess in the length of the west wall was ascertained to have been disposed equally on both sides. This irregularity in the Norman plan had been obviated within the church by the addition of large clusters of pillars towards the east and south; but above, where the Norman architecture remained in all its original simplicity, the difference was perceptible. Four storeys corresponded in design, the next below was plain, and so was the lower storey, with the exception of the doorway on the west side; but the intermediate space was enriched with a Norman window on the west, and doubtless with another on the north side. The walls were battered all the way up, some divisions more than others; their bulk was thinned on the outside by the diminution of every stage, and their gravity reduced on the inside by a series of semicircular arches on each floor. On the angles were pilaster buttresses of several thicknesses; that to the north-west enclosed the staircase. The design may be remarked as possessing two distinguishing and very interesting features: one, that the original arches throughout the design enclosed other arches; the second, that Norman and Pointed arches of coeval date were associated in the uppermost range. The Pointed arches enclosed the Norman; both had mouldings, columns, capitals and bases alike. A single torus moulding of the same size as the column from which it sprung constituted at once the figure and the ornament of the arches. An indented line on some of the capitals and cornices is the only ornament remaining to be noticed.

The walls of this noble tower were cracked on all sides between the base and the middle line of its elevation. Time and alteration had contributed to the defects which ended in demolition. Their operations have been gradual and perhaps have not been greatly retarded by the efforts which were made half a century ago to tie the mutilated walls together. To these another cause may be added for the dilapidated state of this building, namely, the inferior quality of the mortar, which had lost its binding property in the lower half of the walls, but retained the strength of the stone above. The walls were 7 feet broad at the base and upwards of 3 feet at the summit, composed throughout of rubble and a large proportion of lime, faced on the outside and inside with squared masonry, not bonded through the wall in any part. The strength of a Norman wall is in its core; when this crumbles and falls away, as in the present instance, the fate of the building is decided. But I question the modesty and justness of any reflection upon the failure, so to name it, of a fabric which has stood full six centuries and a half. The builder must have been a skilful and a honest workman; and that his labour was duly appreciated by the architect of the fifteenth century will be admitted by those who remember the laborious and difficult alterations he effected for the sake of preserving this tower and obliterating all traces of its Norman character in the interior of the cathedral. But before I describe these alterations I will conclude my remarks on the masonry, which had been carefully squared and joined together; but the size of the courses and the line of the joints were uneven. In no instance were the blocks large enough to stretch into the second member of the jambs; the same remark applies to the buttresses; it was throughout a fine and well-

wrought but thin ashlar, in the three uppermost tiers very perfect, but betraying below the middle, where it was detached from the cement, its dangerous condition. Some of the arches were formed with keystones, others without, as accident determined; and it is evident that the smaller arches, consisting of six or eight narrow stones, were constructed without centres; none of them were semicircular, but all exceeded the semi-diameter in height. The architect who spared this magnificent tower from the ruin which lighted on the Norman nave planned and executed a skilful design for preserving the interior uniformity of the church. The original arches, however graceful in form or tastefully enriched, would have ill accorded with the light and splendid character of the Pointed architecture which Prior Chillenden adopted for the nave. It became necessary not only to change the form of arches and pillars, but also to enlarge the openings, and it is probable that with the lower part of the south and east sides of the tower, the internal angle was entirely removed to make room for the present clustered pillars. At all events, if the angle was not wholly destroyed, it was so much reduced in bulk as to be inadequate for the support of the incumbent weight without the addition of the new stonework. But it is the operation previous to the alteration, and necessary to its success, which I shall more particularly describe as evincing the ability and perseverance of our ancient architects in the execution of their labours. On three sides of the tower, the north, east and south, above the openings, Pointed arches were built into the walls, of irregular masonry and coarse construction, but sufficiently strong and compact to bear the pressure from above, while the wall below was either wholly or in part taken away. The erection of this ingenious contrivance was slow and difficult in this strong and ponderous building. After the form and size of the arch had been marked on the wall, the masonry was removed in small portions, and immediately supplied by the springer of the new arch, kept flush with the old wall. In this manner the work was advanced till the discharging arch was completed. It was interesting to examine a contrivance thus admirably and successfully executed several ages ago. The two internal arches stretched quite across the walls, and abutted against the piers, and were better shaped and more carefully built than the external one towards the north, intended to uphold only a portion of the weight which otherwise would have pressed on the arch of a lofty window. I have preserved an accurately delineated representation of this arch; and it will show how little attention was paid to the size and shape of the stones employed, so that they formed altogether a compact mass, and served the purpose for which they were intended. The broken line of one side was an accident in the original construction. Had it happened after its completion and the removal of the wall underneath, it would have proved injurious to the building, over which, however, it remained till its destruction without a flaw. If the preservation of this tower had not been an object of considerable moment, so much care would not have been taken as we have seen was resorted to for the purpose of securing it from accident during its necessary internal alteration; but after three centuries and a half the architect of the fifteenth century will surely escape reproach, though I attribute to his labours the causes in part of the subsequent weakness of the building. By means of the arches he so dexterously constructed an undue weight was forced upon the angles. The structure was three centuries old in his days, but nevertheless did not yield to time and alteration till it had numbered full twice that period. The angles towards the lower part were bulged and crippled throughout the substance of the wall, while those of the upper part retained their firmness, and exhibited no signs of decay.

Canterbury, notwithstanding its losses, is still rich in the treasures of ancient architecture. But the destruction of its noblest and most interesting specimens of the Norman style—the tower just described, and a splendid relic of the tower of St. Augustine's Monastery—has severed the chain of illustrations belonging to the records of its architectural history. Canterbury is not without specimens of Early Norman architecture, but these are scarcely regarded in the midst of a transcendent display of the same style in its richest costume, combined with the grandest dimensions and the most highly finished decoration. The Norman nave might have been as frugal of ornament as the western tower, but whatever were its features, it was entirely swept away in the fifteenth century, and its demolition must have proved a work of great labour—labour, nevertheless, surpassed by that which the ingenuity and admirable skill of the architect of Gloucester Cathedral imposed upon himself when he executed his design of spreading a screenwork of stone of a light and exquisite pattern over Norman architecture of the most plain and robust character.

M. Saladin has been appointed architect for the buildings which the Government of Tunis have resolved to erect in connection with the International Exhibition of 1900.

GROINED VAULTS.

THE stupendous vaulting of the Temple of Peace at Rome was a groined vault. In the construction of this vault the Romans showed a knowledge which would have been admired in the latter part of the Middle Ages, and the idiot Emperor Claudius a discrimination in the choice of his architect not inferior to the inspired selection of Giulio II. and Paolo III. The vaulting of the great hall at the Baths of Diocletian is of the same character, and equally deserving of respect as that of the Temple of Peace.

It was the practice of the Freemasons, to whom we are indebted for the vaults which secure our cathedrals, to reduce all the pressures in a building, whether vertical or lateral, to certain principal supports; their vaults were composed, "ex lapide et topho," of ribs and panels—the one of good freestone, the other of light sandstone or chalk; their supports were piers and columns, and a wall with them was held to be merely an enclosure. The objection to this principle, "that stone would crush when subjected to the pressure of great weights reduced to a small surface," may be answered by a reference to the columns in Gothic cathedrals.

Gauthey, in the fourth volume of "Rosier's Journal de Physique," speaks of a column in All Saints, Angers, 24 feet high, 11 inches square, which sustains 60,000 lbs. He says this is only one-seventh of what would crush it. There is a column in the morning chapel at Lincoln Cathedral equally thin in comparison to its height. This column stands insulated in the centre of the chapel, so that it sustains eight-twentieths of the whole vaulting which covers the chapel. The columns which support the roof of the galleries of the Patio de los Leones, of the Alhambra in Granada, are nearly as thin in proportion to their height. A pillar twenty-six times its diameter in height would have been to the Ephesians, as Pascal styles the Jews, a continue miracle. It would be pleasant to listen to a dialogue between the shades of the architect of the hexastyle hypæthral temple at Pæstum, and the architects of All Saints of Angers, or Lincoln Cathedral. We must say of the former "professus grandia turget."

At the revival of Roman architecture the adage "Pondus addit robur" became proverbial. The different interpretations exemplified in the buildings of different ages are amusing. In the groined vault we may perceive the origin of all the improvements which the Freemasons made in the art of vaulting.

The Romans in their bridges endeavoured to reduce the dimensions of the piers, and to render the vaults of their arches more nearly in equilibration than the line of road would generally permit, by means which, in some measure, surprise us by their clumsiness, when the more elegant mode by groined vaulting had been discovered. The practice to reduce the size of the piers was by constructing small arches in the piers themselves above that part of the pier where adequate resistance had been obtained for the lateral thrust of the arch, as may be seen in the Pont du Saint Esprit over the Rhone, in Languedoc, at the bridge of Merida, in Spain, and Ponte Fabrizio, at Rome. A similar mode was adopted at the Ponte Senatorio, now Ponte Rotto, by Pope Gregory XIII. This method had also the additional advantage of affording more waterway. Tunnels have been sometimes worked in the piers with the same view—as in Ponte Sisto, built by Pope Sixtus IV. upon the site of the ancient bridge of Janiculense, and as at the Pont de Toulouse, in France, and at the bridge of Glasgow, over the Clyde. Perronet, the French architect, not only formed tunnels in the piers, but also over the haunches. The Welsh mason Edwards, in the wonderful bridge over the Taff, in Glamorganshire, learnt from experience what Perronet's theory had taught him. Over each haunch of the arch of the Pont y Prydd there were three tunnels in the breast of the arch. The mode recommended to be adopted at Blackfriars Bridge by Dr. Stukeley, "Phil. Trans.," June 1760, and which had been adopted in consequence of the sinking of one of the piers of Westminster Bridge, is very ingenious and appears particularly applicable in many cases where circumstances require a number of small arches.

Perronet, in the bridge of St. Maxence on the river Oise, adopted another mode of reducing the size of the piers, which was by supporting his arches on columns instead of single piers; so that there are openings longitudinally through the bridge, by which the size of the supports are reduced by a mass of material equal to the intercolumniations. The parts of the arches over the intercolumniations are supported by arches something resembling the inverted concave conoidal vault of King's College Chapel, Cambridge, piercing the great arches, but the weight, nevertheless, is spread on the whole surface of what would have been the base of the pier. This method may be considered as an introduction to groined vaults in the arches of bridges, a practice which would be more securely followed by adopting the Gothic manner of "arcs doubleaux."

When considering the knowledge of vaulting possessed by the builders of the thirteenth and two following centuries Sir John Robison observes:—"An art so multifarious and so much

out of the road of ordinary thought could not but become an object of fond study to the architects most eminent for ingenuity and invention; becoming thus the dupes of their own ingenuity they were fond of displaying it where not necessary." The ingenious and promising invention of substituting ribs for the groins of a groined vault required the practice of increasing the height of the generating curve over the sides of the space to be covered. When the arch over the side of a polygon is a semicircle, the arch over the diagonal becomes elliptic, the longer axis horizontal. By making the arch over the side a semi-ellipse, the short axis horizontal, the arch over the diagonal becomes proportionally elevated. If the arch over the diagonal in an octagon plan be semicircular, that over the side will become elevated in proportion to its width, as the radius 1 to 7653, the side of an inscribed octagon. At the Baths of Diocletian the crossing vaults of the great hall are elliptic, the short axis horizontal, and of such a curvature that the groins or arches over the diagonals of the side-groined vaults are semicircles.

Gautier says that pointed arches were used in bridges, churches and other buildings, "par la faire moins de pousseé." Sir Christopher Wren makes a similar observation, adding that these arches required less centering and thinner stones.

In every arch the summering of each voussoir decreases from the springing to the vertex, and in an arch whose tangent at the vertex is horizontal, the summering necessarily vanishes at that point. The thickness which is given to an arch at the vertex has relation to what may be considered a sufficient summering. Hence the more oblique the tangent of an arch at the vertex may be, or, in other words, the more acutely pointed the arch, the less thickness of material will be required. By a parity of reasoning it may be shown that the more acute the arch may be at the vertex, the less lateral thrust will be on the abutment. These geometrical and mechanical facts must necessarily have led to the adoption of the semielliptical vault, the short axis horizontal or the pointed arch. Payne Knight, who was eminent as a scholar and a man of taste, observes that "the pointed arch is the primitive arch, of which the earliest instance known in Europe is the emissarium of the lake Albano, built during the siege of Veii (394 years before Christ), before either the Greeks or Romans knew how to turn any other kind of arch, for, as this may be constructed without any centre by advancing the stones in gradual projections over each other, and then cutting off the projecting angles, its invention was obvious and naturally preceded those constructed upon mechanical principles, of which, I believe, there are no examples anterior to the Macedonian conquest." The account of this pointed arch is manifestly copied without thought from the work of some ignorant person; an emissarium may be conceived to be an arch. The first covering of an enclosed space, whether by wood or stone (not a lintel), was and must have been in the form of a pediment; the roofs of the queen's chamber and of the passage to the tomb in the pyramid of Egypt are an unnecessary confirmation. This pyramid, we are told, was built soon after the Trojan war, about twelve centuries before the birth of Christ.

Were it admitted that this emissarium had been hollowed out in a form like that of a pointed arch, nothing could be gained from this solitary fact in answer to the questions, When were arches first known? What were the forms of these arches? Seneca, Epis. 90, denies to Democritus the invention of an arch, "ut lapidum curvaturâ paulatim inclinorum medio saxo allegaretur;" such an arch as this must have required a centre. Democritus flourished sixty years before the siege of Veii. The question to be agitated, if any inquiry upon the subject were worth the labour, is, When were the arches (composed of voussoirs) first in use? To which a satisfactory answer has not yet been given. Lintels may be hollowed out into any shape, and the stones which project over one another like steps, and covering a room, may be also cut into any shape. The stone covering over the Temple of Mylassa could not have been cut out into the form of a pointed arch, but might have been cut into an extremely flat ellipse or scheme arch. The whims and caprices of masons are not to be attended to. The vault of the Salon en Forma de Tribunal of the Patio de los Leones of the Alhambra at Granada is of the early construction by inverted offsets, and is hollowed out into fantastical shapes which could have suggested themselves only to the mind of an Arab architect. Sir Christopher Wren says that the pointed arch was derived from the Saracens. We must not apply to Granada or Cordoba for confirmation, although we may see there the trefoil and cinquefoil arch.

Sir W. Gell, in his "Itinerary of Greece," 1810, says:—"Between Krabata and the Acropolis of Mycenæ is the Treasury of Atreus; the apartment itself consists of a circular dome, in shape like a beehive, 47 feet 6 inches in diameter and about 50 feet in height. This dome is not composed of stones which form part of the radii of a circle, as in an arch, but is constructed with horizontal courses, the inside of each stone being curved in such a manner that the whole has the appearance of a regular vault. Though a stone is now wanting near

the top the roof seems to be in no danger of falling. Vaults of this construction are to be found among the ruins of the ancient cities of Sicily. About 3 miles from Noto, in the district of Falconara, is a peninsula covered with ruins of the ancient city of Macara. Here, in a place called the citadel, are buildings covered with large stones placed horizontally, and having, like that of Mycenæ, internally the appearance of a dome." He further says, "It is of little consequence whether these treasuries or magazines were erected by Atreus or his predecessors."

Horace Walpole has happily remarked that "it may as well be asked who invented pure Italian, as who invented the pointed arch"; and he might have added La Fontaine's maxim in regard to another subject of jealousy:—

Quand on l'ignore, ce n'est rien.

Quand on le sçait, c'est peu de chose.

From the time of Pericles, through the ages of Augustus, Justinian and the Normans, every succeeding five centuries to the fifteenth, like a lustral cleansing, is remarkable for the alterations in architecture, and the alterations appear to have arisen from the modes of covering the spaces enclosed for public worship. It is also remarkable that the prevention of fire has been the mother of the inventions which have characterised those times. Parsons, in his "Travels in Asia and Africa," says "that in Aleppo there is no fear of fire, their houses being of stone and the ceilings arched." Dr. Johnson, describing the palace in the Happy Valley, in "Rasselas," says "that the roofs were turned into arches of massy stone, joined by a cement that grew harder by time; and the building stood from century to century deriding the solstitial rains and equinoctial hurricanes without need of reparation." Thick stone walls will remain to mark the site of a building, but vaults alone can preserve the building itself. It is the roof which makes the house.

Previously to vaulting the naves of the cathedrals round-headed arches were general, and there were few examples either of rib or panel vaulting, pointed arches, pinnacles or buttresses. While vaults were confined to low buildings, as crypts and the aisles of cathedrals, it is obvious that the thick walls of the Saxons and Normans would be able to resist their thrusts. The numerous arches at the Alhambra in Granada, at the Mosque at Cordoba, probably built about the eighth century, are elliptical horseshoe arches.

In the vaulting of the aisles of Durham and Canterbury Cathedrals are to be observed the "arcs doubleaux," and groined ribs in roundheaded vaults. In the naves of the same buildings is the same character of vaulting, except that the arch of the vault is pointed. Some vaults of this kind are to be distinguished from others by the position of the stones of the vault between the ribs, which instead of being parallel to each side of the plan as in Roman groined vaults, take a mean direction between the groined rib and the ribs of the arches over the sides, whence they meet the vertex at an acute angle and are received by stones running along the vertex, cut in the form of a ratchet. The advantage of this method consists in requiring less centering and originates in the position of the ribs at the springing.

From these beginnings vaulting began to assume those practical advantages which the joint adoption of the pointed arch and ribs was calculated to produce.

Gray, in a letter to Mason, says:—"Gothic architecture, previous to the time of Henry III., is of a clumsy and heavy proportion, with a few rude and awkward ornaments; then all at once came in the tall and picked arches, the light clustered columns, the capitals of curling foliage, the fretted tabernacles and vaultings, and a profusion of statues, &c., that constituted the Gothic style, together with decreasing and flying buttresses and pinnacles on the outside." If the antiquary will not ascribe the ornaments characteristic of the Gothic architecture of the times of Henry III. and succeeding ages to the vaulting the naves of the cathedrals, nor the pointed arch to the necessity for its production, but only to fortuitous circumstances, it must be acknowledged that the contemporaneous production is remarkable, especially as those ornaments and that form are useful only in vaulted buildings.

The second step differed from the first, inasmuch as at the vertex of the vault a continued keystone or ridge projects below the surface of the vault and forms a feature similar to the ribs. But here it was necessary that the ridge should be a stone of great length, or having artificially that property, because its suspension by a thinner vault than itself would be unsafe unless assisted by the rib arches over the diagonals and side, a distance equal to half the width of the vault. To obviate this objection other ribs were introduced at intervals, which may be conceived to be groined ribs over various oblongs, one side continually decreasing. This practice had a further advantage, as the panels or vaults between the ribs might become proportionally thinner as the principal supports increased. It was then that the apparent magic hardness of pointed vaulting and the high embowered roof began to display itself; from slender

columns to stretch shades as broad as those of the oak's thick branches, and in the levity of the panel to the rib to imitate that of the leaf to the branch.

On comparing rib pointed vaulting with Roman vaulting, it will be invariably found that the rib itself is thinner than the uniform thickness of the Roman vault under similar circumstances, and that the panel, which is the principal part of the vault in superficial quantity, sometimes does not exceed one-ninth part of the rib in thickness. The Gothic architects, it has been expressively said, have given to stone, an apparent flexibility equal to the most ductile metals and have made it forget its nature, weaning it from its fondness to descend to the centre.

VALUE OF LAND IN ENGLAND AND SCOTLAND.

AN interesting case which suggests the difference between the principles of land valuation in England and Scotland is the subject of arbitration. The land in question, which belongs to Lord Lamington, is required for the construction of a reservoir by the Airdrie and Coatbridge Water Company. The *Glasgow Herald* has published the following notes of the arbitrator Sheriff Jameson:—

Edinburgh, June 30, 1897.—The oversman having considered the proof and whole process and heard counsel for the parties proposes to find that the sum due and payable by the respondents to the claimant as purchase-money and compensation for taking the 74½ acres mentioned in the minute of reference is 5,155£ sterling, with interest at the rate of 5 per centum per annum from July 15, 1894, until paid. Further proposes to find the claimant entitled to his expenses as the same may be taxed if required by the auditor of the Court of Session, the expenses of and incident to the proof allowed by interlocutor of April 7, 1896, to be taxed as between agent and client. Allows either party to make representation against the above findings within fourteen days from the date hereof.

(Sgd.) ANDREW JAMESON.

Text of the Note.

In this arbitration the claimant claims to be compensated on the footing that the land taken by the respondents is to be valued not as pastoral land, but as land having a special value as the site of a reservoir, and having therefore what has been termed somewhat loosely, as it appears to me, a "commercial value." Alternatively the claimant supports his claim by evidence of the value of the land viewed as part of a pastoral farm, which is its present use. A good deal has been said in the course of the proceedings about a difference of principle in valuation between the witnesses for the claimant and those for the respondent, but it appears to me that the difference between the parties is perhaps one regarding the methods rather than the principles of land valuation. I hope I may be pardoned adverting at this time of day to some elementary principles of valuation, regarding which apparently there is no difference of opinion between the parties.

In the first place, it is well settled that in valuing land under compulsory powers the arbiters or oversman are bound to take into consideration not only the present value of the land to the owner, but also any potential or prospective value that it may possess. In ascertaining what potential or prospective value any piece of land possesses, the first question is, what are the uses to which it can be adapted? And the next is, what are the probabilities or possibilities of its being wanted for these uses by the owner himself or by members of the public (including companies and corporations) other than the persons in whose favour the Legislature has granted compulsory powers? It is the first of these questions that has given rise to the term "adaptability," and "adaptability" as is laid down in the case of the Countess Mary Osselinsky v. the City of Manchester, reported in the appendix to Brown & Allen on "Compensation," is an element that ought to be taken into consideration in fixing the value of land. But it is obvious that "adaptability" of land for any purpose, though it ought to be taken into consideration, cannot justly be held to add to the marketable value of land to the owner, unless it can be shown that at the time of the land being taken there was a probability, greater or less, of the land being required for that purpose by some person other than the purchaser holding compulsory powers.

What is Marketable Value?

It is this probability that raises "adaptability" into "marketable value," and in my opinion "adaptability" for any purpose, though it may be considered, can have no value put on it unless by reason of such "adaptability" a probable demand for the land possessing the adaptability is proved. To illustrate what I mean, take the most familiar example of prospective value—namely, the prospective value of agricultural land for building purposes, it may be said that so far as intrinsic qualities are concerned, most of the land in the country is

"adaptable" for being built upon, yet unless by reason of proximity to a town or the establishment of a new industry in the neighbourhood, or some such cause, there is a probability of any particular piece of land being required for building purposes within a moderate period of time, no value will be put on the land merely because it is adaptable for being built upon; while, again, if there is a probability of its being required for building purposes, but not till after the expiry of some years, then if a building value is given it will be discounted according to the number of years which will probably elapse before the land is wanted for building. Again, taking reservoir sites, I have no doubt that throughout Scotland, and especially in the Highlands, railways have intersected and spoiled what might have been admirable sites for reservoirs, but it never entered the mind of any proprietor or his advisers to make a claim in respect of such land on the footing of its being land adaptable for reservoirs, for the obvious reason that there was no demand whatever for it as such.

What uses Land is adaptable for.

It has always been the practice in Scotland in arbitrations under the Lands Clauses Acts to consider what uses land is adaptable for. I may mention that in an arbitration in which I was oversman regarding the value of Barry Links, in which the trustees for Lord Dalhousie were the claimants and the War Office was respondent, and in which the award amounted to about 38,000*l.*, evidence was led and considered as to the prospective value of various portions of Barry Links as adaptable for use as (1) a rifle range, (2) an artillery range, (3) a rabbit warren, (4) ground for grazing sheep on, (5) small arable holdings, (6) building ground so far as it adjoined certain villages, and (7) irrigation ground for the sewage of the town of Dundee. But in no arbitration in Scotland, so far as I know, has value been given for bare "adaptability" apart from a probable demand for the land for the purpose to which it is said to be adapted, such demand being either inferred from surrounding circumstances other than the circumstance of a party coming to take under compulsory powers or proved by direct evidence. It seems that it is otherwise in England, and the valuation put on the site in question in this case by all of the claimant's English witnesses seem to be based on these two grounds—(1) That the land now in question is adaptable for being used as the site of a reservoir; (2) that 150*l.* per acre (to quote Mr. Fenwick's figures) is a value willingly given for reservoir sites in England, and represents what a reservoir site is worth between parties purchasing and selling the same. Then it seems to be assumed from the fact of the respondents having come to this site that either Lord Lamington himself would have utilised it as a reservoir or the promoters of some other similar scheme would have come to take it. It is only fair to Mr. Fenwick, whose evidence was given with the greatest frankness and clearness, to say that he apparently admits (p. 80 C of proof) that mere adaptability apart from demand would not form an element of value. But judging generally from the evidence of the claimant's English witnesses in this case, who are gentlemen of high character and of great experience in compensation cases, it would appear that a practice has grown up among arbiters in England of invariably giving high rates for reservoir sites apart from the question whether in any particular case there was any probable future demand for the site other than the demand from the parties taking it under compulsory powers.

Difference between Scotland and England.

This practice may have arisen from the circumstance that there is comparatively little ground in England at high elevations and suitable for reservoir sites in proportion to the extent of the rest of the country and the density of the population residing therein, with the result that all land in England at a certain elevation above the sea-level and adaptable for reservoir purposes is assumed to possess a recognised marketable value in respect of the qualities which it undoubtedly possesses. If this is so I can only say that a different state of circumstances exists in Scotland, where even in what are called the Lowlands there is hardly a single town or village which is not within reach of high-lying ground where reservoir sites may be readily obtained. But I venture to think that even in England the practice (if it exists) is an unfortunate one, and we have heard in the present proceedings of a case which, I think, shows the danger of determining any particular case by rules of fixed values spoken to by witnesses from their experience in other and possibly differing cases. The case I refer to is the case of the Swansea Waterworks, spoken to by Mr. Fenwick. In that case a syndicate had purchased, at public auction, a sheep farm, with hill-top pastures, on the ridge between Brecon and Swansea, for the sum of 11,500*l.* The extent of the farm was 5,000 acres. A year and a-half after the purchase the Corporation of Swansea, having obtained compulsory powers to make a reservoir on said farm, gave notice to treat, and the case went to arbitration, when a sum of 12,370*l.* was awarded for 140 acres

which was taken by the Corporation for their reservoir, plus an easement through a tunnel in a hill for their conduit. In that case the owners of the land could not point to any other community which was likely to want that reservoir site of 140 acres. As Mr. Fenwick, who advised the claimants, puts it, "We said simply it was the value of a reservoir site, and one customer at all events wanted it." This case is certainly a remarkable one. The price which the estate fetched by public auction a year and a half before the arbitration shows clearly that the land possessed no market value by reason of its adaptability as a reservoir site. It further appears that it could not be proved that there was any probable demand for it as such except by the persons to whom the Legislature had granted compulsory power to take it, and yet an arbiter awarded 12,370*l.* for 140 acres out of an estate of 5,000 acres which a year and a half before had only fetched 11,500*l.* In other words—putting aside the easement—land which had sold one year at 2*l.* 6*s.* per acre was within two years held to possess the value of 88*l.* 7*s.* per acre or thereby. In my humble opinion, and with all deference to the superior experience of valuers who support the practice, I cannot help thinking that the public of Swansea were subjected to a most extortionate charge, and that the practice which leads to such a result cannot be a sound one. It has been said by some of the claimant's witnesses in this case that the practice of giving values apparently for adaptability pure and simple is borrowed from the practice in the north of England regarding land taken for railways, and it appears, according to Mr. Storey's evidence (p. 63 C of proof), that if, by reason of land being level, a railway can be made cheaply through a part of an estate, the proprietor has the right to claim for the facilities for making a cheap line, and he further informs us that the same practice was applied to the pipe track in the Manchester water scheme. He says:—"It was admitted that the pipe track going on the contour saved them 60,000*l.* going through a deep cutting. I am speaking roughly with regard to figures, and it was proved that the landowners had a right to make a special claim for the track going on the contour, although the land down below was more valuable."

The Element of Adaptability.

I can only say that the practice of which the above are examples appears to be wholly at variance with the well-recognised rule that what is to be valued is the value of the land to the person from whom it is taken, and not the value to the person who takes it under compulsory powers. It further appears that where the element of "adaptability" enters into a valuation, it is a practice in the north of England when there is a difficulty as to what value to put upon "adaptability" in land taken under compulsory powers to calculate what the undertaking for the purposes of which the land is being taken will pay when it is once set agoing, and to fix on one-fifth or one-seventh or one-tenth, as the case may be, of the profits of the enterprise as what should be paid to the owner of the land. This practice, which is said to be a "fairly-established" one in the north of England, is spoken to by Mr. Storey (p. 55 F and 66 C of the proof), and it seems to have been applied in the case of railways as well as of reservoirs, and my friend Mr. Gow, one of the arbiters, considered that this practice ought to be applied in the present case. With all deference to the great experience and knowledge of Mr. Gow as an arbiter and land valuator, and also to the opinion of the claimant's skilled witnesses, I must say that it appears to me that this method of valuation is faulty in principle. It professes to fix the value of the land to the owner by considering how much profit the purchaser will make out of it and then giving the owner a share of that profit. I am aware that this is attempted to be justified by assuming that if the particular company or corporation taking the "adaptable" land had not done so some other company or corporation would have done so, and that there being thus a demand for the land for a particular purpose its value is represented by whatever sum the hypothetical company or corporation could afford to pay for it, and might have offered to the landowner for it, and this sum again has to be arrived at by considering what profits the hypothetical undertaking would produce. This is what has been termed "commercial value." I must say this seems to those accustomed to the Scottish practice a strange method of land valuation. It proceeds on the footing of holding adaptability proved, as it generally is, by the fact of promoters of an undertaking armed with compulsory powers applying for the land and by then assuming hypothetical purchasers as competitors. The method results in an evasion of the well-known rule already adverted to, and which I find laid down by Mr. Cripps, Q.C., in his "Law of Compensation" thus: "The basis on which all compensation for lands required or taken should be assessed is their fair value to the owner as at the date of the notice to treat, and not their value when taken to the promoters. The question is not what the persons who take the land will gain by taking it, but what the person from whom it is taken will lose by having it taken from him."

Action of the Legislature.

It was said in the course of the present proceedings that the Legislature has practically sanctioned these methods of valuation, because attempts have been made to get clauses inserted in special Acts regarding railways in England, limiting the arbiters or umpire in their valuation to the actual agricultural value of the land, and that Parliament had always refused to insert such clauses. I do not think this proves anything, because I take it that Parliament would never consent in a matter of what must be called general law to alter the provisions of Acts such as the Lands Clauses Acts by contradictory provisions in special Acts. But I am not surprised that, looking to the practices and methods I have referred to, there should, as one sees in the newspapers, be occasional remonstrances in England regarding the enormous sums given in compensation cases as compared with the actual value of the land taken, and I would not be surprised if, following the example set in the Allotments Act, some legislation were by-and-by to be introduced defining more particularly the general law on the subject of compensation for land taken for public purposes as that law is laid down in the Lands Clauses Acts. I need scarcely point out how in practice a method of valuation such as I have referred to is apt to be difficult and misleading. Few things are more problematic than the ultimate success of any commercial enterprise, be it a railway scheme or a water supply scheme, and it seems to me most hazardous to depart from ordinary methods of land valuation, and to have recourse to methods which (apart from all objections to principle) are fraught in practice with elements of uncertainty and difficulty, and with enormous possibilities of injustice. In the present reference Mr. Copland, who I have no doubt foresaw the difficulties of reconciling the practice to which he has been accustomed with the novel methods of valuation in vogue in the north of England, repudiates these methods, but takes refuge in a method which leads to practically the same result. He supposes that Lord Lamington is to become a water merchant on his own account, is to obtain compulsory powers from Parliament for taking his pipes for thirty miles along public roads, and is to supply water at profitable rates to anyone he can induce to buy from him between Coulter and Glasgow, and Mr. Copland then arrives at the value of the land to Lord Lamington by a consideration of the profits he (Lord Lamington) would make out of this novel enterprise. This is very ingenious, but the hypothesis on which it is based is so improbable that I really do not think it worth while to consider it further.

Circumstances of the Case.

To come to the present case, there is little question that the land to be taken is in some respects adaptable for the site of a reservoir. Had it not been so the respondents would not have thought of taking it for that purpose. But I may here note, though I shall revert to it hereafter, that the site had one important disqualification which it was not known to possess when the respondents procured their Act, namely, that suitable clay for forming the puddle trench and wall of the embankment was not present either in the land to be taken itself or the near neighbourhood. The next question, however, is, Was there a reasonable probability of this site being wanted for a reservoir by any persons or communities other than the respondents? Mr. Copland, the first witness for the claimant, gives on pages 21 and 22 of the proof a list of all the towns and villages which might be supposed some time or other to require a reservoir site at Cowgill, but he says on page 32, letter C, that with regard to the towns and villages on his list, all of them, except some very small villages, have got a supply of water with the possible exception of Carstairs. It is instructive to notice that while Mr. Tait, the engineer to the Wishaw Commissioners, speaks to the reservoir site in question as being of sufficient elevation to supply Wishaw and Motherwell, yet, although the Wishaw Commissioners were looking out for a site for a reservoir before the present respondents, they never thought of approaching Lord Lamington (p. 14, F.G.), because a reservoir at Cowgill would have been too expensive for them, and they accordingly intend now to go to a place called Dunsyre. It is true that Mr. Tait says (p. 116 C of proof) that Motherwell and Wishaw in combination might have been a customer for Lord Lamington's site at Cowgill, but that apparently is out of the question now, and Mr. Tait has to admit that agreements between towns such as these I have been speaking of are not very easy to make, and accordingly Wishaw has got a scheme of its own, and is to have a reservoir at Dunsyre, where a reservoir can be constructed much more cheaply than at Cowgill.

Result of the Evidence.

In short, the result of the evidence led is that the claimant has failed to show (first) that any single town or community referred to in the proof could alone afford to go to Cowgill, and (second) that the claimant has failed to show that any combination of communities would do so. It is true that a general

suggestion has been made that at some future time a combination of communities, or perhaps a district of the county of Lanark, might desire to make a reservoir at Cowgill; but in the first place this is an entirely problematical view, and against it I think it must be assumed that if any considerable combination of communities, or a large district in Lanarkshire, wished a new or additional water supply, they would almost certainly choose a site where a reservoir of much greater capacity could be formed than is possible at Cowgill. But in considering the question of probable competition for a reservoir site at so high a price as 150*l.* per acre or upwards, it is very important to observe that Cowgill is by no means the only possible site for a reservoir in the Upper Ward of Lanarkshire at an elevation capable of supplying water to the towns and villages in the lower parts of the county, because no less than five sites, apparently all of them possible sites, were mentioned in the course of the evidence—viz. Coulter, Camps, Wandel, Midloch, and the Kyne Water. Now, I think it very certain that if any possible customer had come to Lord Lamington and been told that he would have to pay 150*l.* per acre for a site at Cowgill, he would very speedily have gone down the water to Coulter or across the country to some of the other places I have mentioned, where, doubtless, he could have got a reservoir site at a very much less price. But since this case was commenced a fact has emerged, which, I think, makes it extremely improbable that any customer other than the present respondents would have been found for Cowgill reservoir site, and that is the want of clay at or near Cowgill suitable for making the puddle trenches and walls of the proposed reservoirs. The result has been that the respondents have been obliged to get clay elsewhere, which will cost them when delivered at Cowgill something like 20,000*l.* At the time when the respondents procured their Act they were under the belief, induced by insufficient investigation, that serviceable puddle clay would be found in the site of the reservoir, and from the additional evidence in the case it seems certain that if they had not entertained this belief they would never have gone to Cowgill at all. On the whole matter I am of opinion that it is not proved that at the time when the land in question was taken by the respondents there was any reasonable probability of its being wanted as a reservoir site by any other person or community. I therefore am of opinion that it possesses no prospective value as a reservoir site, and falls to be valued according to the use to which it is at present put.

Character of the Ground.

The ground taken forms a long strip of sheltered and comparatively flat land in the midst of steep, high and unsheltered hills. Having for ages received the washings off the surrounding hills, the soil partakes of an alluvial character, and the herbage, consisting of grasses, rushes and other plants, is strong and luxuriant compared with that on the adjoining hill pastures. It is situated about the centre of one of the hirsels of the farm of Baitlaws, and may well be termed the heart of the hirsle. The value attaching to it is not to be measured by the number of sheep which, if it were fenced, could feed on it all the year round. It supplies to a large number of sheep a daily and most salutary change of food in summer and a store of natural hay in winter. It serves as a shelter in times of winter storms and as a sheltered and warm spot for ewes and lambs in a cold spring, such as we have just passed through. It contains any number of excellent watering-places, which the surrounding hills are very deficient in. All these advantages the farm of Baitlaws will lose by the ground being converted into reservoirs. Further, when occupied, as it will be, by two sheets of water fenced into one block, it will form for a long distance a complete barrier against sheep crossing from one side of the valley to the other when they might wish to do so on account of the direction of the storm, and it will lead to greater difficulty and expense in herding the sheep, and probably to other inconveniences in the working of the farm. I cannot, after a careful consideration and reconsideration of the evidence, avoid the conclusion that the farm of Baitlaws will let for about 110*l.* less a year than it formerly did, owing to this piece of land being taken out of the heart of one of the hirsels.

Award as Compensation.

It is, however, right to divide the amount I propose to award as compensation into what should be put upon the land taken and what should be reckoned as severance and other damage of all kinds to the rest of the farm. As sheep farms are generally valued, not according to acreage, but according to the number of sheep they carry, I proceed to inquire how many sheep will require to be sent off this farm owing to the taking off of the 74½ acres in question. This is a question which it may reasonably be thought can best be answered by the tenant of the farm and his shepherd. The tenant puts it at 10 score and the shepherd at 10 or 12 score. But it is possible that both these excellent persons may in the circumstances take a somewhat pessimistic view of the future of the hirsle

after being deprived of a part of it on which they naturally set a high practical value. So I take the lower figure of 8 score spoken to by Mr. Glendinning, Mr. Kennedy and Mr. Archibald, all very experienced gentlemen. I am not much impressed by the respondents' witnesses on this matter. Most of them know nothing whatever about sheep-farming, and although Mr. Hamilton and Mr. McDougall are entitled to respect as skilled sheep-farmers, I think that neither their methods of inspection nor valuation in this case are entitled to the same weight as those of the claimant's witnesses. The next question is the rate per score to be taken. Now 8s. per sheep overhead is the present rent of the farm, and I am not disposed in a case of this kind to enter into speculations, more or less fanciful, as to whether rents of sheep farms will go up or down in the future. I think the present rent of the farm is the proper criterion to go by, there being no evidence that it is exorbitant. Nor do I think it worth while to go into the question of the merits (as regards profits) of a blackfaced or a Cheviot stock respectively, regarding which the evidence is conflicting. I accordingly have taken them as equally profitable for the purposes of the present valuation. The next question is as to severance and all other damage, the nature of which I have already sufficiently indicated in the commencement of my remarks on this part of the case. I put that at 72l. per annum. With regard to the damage to the shooting, Mr. Glendinning, the claimant's factor, claims nothing for permanent damage, though he claims a large sum for temporary loss. I think that 50l. a year for an extra watcher and 50l. for disturbance is ample compensation on this head. The difficulty is to know how long it will take to complete the reservoirs, and there is little evidence on this point. The respondents are allowed ten years to complete their works, and I think I may take six of these as representing the time during which there will be more or less disturbance of game. I therefore propose to give 600l. on this head. The figures, accordingly, work out thus:—I. Land taken, 74½ acres, necessitating reduction of sheep stock by eight score at 8s. per head, 64l. at forty-five years' purchase, 2,880l.; II. Damage of all kinds to the remaining lands, 72l. per annum at thirty years' purchase, 2,160l.; III. Damage to shooting during construction, six years at 100l. per annum, 600l.—5,640l.; deduct tenant's interest in damage under head II., 485l.—total, 5,155l.

Wayleave for Road and Pipes.

Edinburgh, June 30, 1897.—The oversman, having considered the proof and whole process and heard counsel for the parties, proposes to find that the sum due and payable by the respondents to the claimant as purchase money and compensation for the servitude right of pipe track and the servitude right of widening and levelling the road mentioned in the minute of reference, No. 1 of process, so as to make it fit for use as an access during the construction of the respondents' works and also on all necessary occasions thereafter for superintendence, inspection and repair, is 545l. 2s., with interest at the rate of 5 per cent. per annum from July 15, 1894, until paid. Further allows either party to make representations against the above findings within fourteen days from the date hereof.

(Sgd.) ANDREW JAMESON.

NOTE.—As is shown by the evidence, there is a very great discrepancy between the sums usually awarded in Scotland and those awarded in England for wayleaves. This possibly arose from the much greater value of land in England over that in Scotland before the times of agricultural depression and the unexampled depreciation which has taken place in the value of all land fitted for growing cereal crops. This being a case of wayleaves over land in Scotland, I am of opinion that Scotch rates ought to rule, and, further, that they are such as amply to compensate the claimant. The wayleaves lie through land situated on a hill side and of little value. With regard to the road, it must be considered that to some extent it was already an *opus manufactum*, and that this fact entitled the owner to something more than if it had been mere hill land. I accordingly think that 4s. per yard is not too much to award in respect of the servitude over the road. This amounts to 279l. 12s. With regard to the pipe track, I am of opinion that 1s. per pipe per yard is a fair allowance, making, for the 1,770 yards at 3s., 265l. 10s., or in all 545l. 2s.

(Initd.) A. J.

Mr. John Rennie Cockerell, whose death, in his sixty-seventh year, occurred at his residence, 36 Westbourne Terrace, Hyde Park, on the 30th ult., was the second son of the late Charles Robert Cockerell, R.A., by his wife Anna Maria, daughter of John Rennie, the celebrated engineer. Mr. Cockerell belonged to the Madras Civil Service and retired on a pension in 1873.

TESSERÆ.

Mezzo-Rilievo.

THE ordinary style of mezzo-rilievo was used for gems, and indeed for all works in this branch of sculpture which required close inspection, and needed no conventional contrivance. A flat style of relief, which is sometimes observable in cameos, was adopted only for the sake of displaying a subject on a different coloured ground, the layers of colour in the stone employed, generally the sardonyx, being very thin. The difference of colour in the ground has, however, the effect of giving roundness to the figures relieved on it, as if, their whole effect becoming apparent, the internal markings disappeared. The figures on the Portland Vase are treated on this principle, and as it was intended to imitate a precious stone (for which indeed it was at first taken), the thinness of the outer layer of colour is also imitated. Such works, however, reduced to one colour in a cast or copy are totally wanting in effect and style. The impressions from intagli or engraved gems, which were used for seals, are never in the flat style of relief, but, however slightly raised, are on the principle of mezzo-rilievo, as above defined. The gems of Dioscorides, the finest of antiquity, are in mezzo-rilievo and often of the fullest kind, as, for instance, the heads of Demosthenes and Io, and the figures of Mercury and Perseus. The same may be observed of other celebrated gems, such as the Medusa of Solon, the Hercules of Cnæius, &c. It is supposed that the same artists who engraved on gems, and who frequently inscribed their names, also executed the dies for coins. The latter are among the finest antique works of art, but of the many thousand existing specimens, there is but one which bears the name of the artist, viz. the coin of Cydonia in Crete, the inscription on which proves it to be the work of Nevanus.

Wren on Gothic Architecture.

Wren made a survey of Salisbury Cathedral at the request of his friend Seth Ward, who was then the bishop; he afterwards made a similar examination of the Abbey of Westminster, and on both drew up reports exceedingly long, circumstantial and curious: "Almost all cathedrals of the Gothic form," he observes, "are weak and defective in the poise of the vault of the aisles; as for the vault of the nave, both sides are equally supported and propped up from spreading by the bows or flying buttresses, which rise from the outward walls of the aisles; but for the vaults of the aisles they are indeed supported on the outside by the buttresses, but inwardly they have no other stay, but the pillars themselves, which, as they are usually proportioned, if they stood alone without the weight above, could not resist the spreading of the aisles one minute." Having described one serious defect in the construction of the Gothic—a defect, however, which, be it observed, is only to be found in such cathedrals as Westminster, where the central nave rises too loftily for the unity which the principles of sound construction require—he proceeds to point out the mistakes of the architect; he is speaking of Salisbury Cathedral, but the sentiments are for all nations and all styles of architecture. "I must assure him," says Sir Christopher, "that building in a low and marshy soil, he did not take sufficient care of the foundation, especially under the pillars. That foundation which will bear a wall will not bear a pillar, for pillars thrust themselves into the earth and force open the solid ground if the foundation under them be not broad; and if it be not hard stone, it will be ground and crushed, as things are bruised in a mortar, if the weight be great. A second fault was not raising the floor of the church above the fear of inundations; many sufficient foundations have failed after the earth had been too much drenched with unusual floods; besides, it is unhandsome to descend into a place. The third fault is the poise of the building, generally the substructions are too slender for the weights above. Besides these defects, the bracing of the walls together with bands of iron to sustain the spire of the tower, however ingenious and neat, is contrary to the rules of good architecture, not only because iron is corruptible by rust, of unequal strength and liable to dissolve and precipitate whatever it supports into ruin, but that the very use of such a material is a proof of defect in construction and could not be required were all parts of proportionate strength and massiveness." It will be considered as singular enough that the dome of St. Paul's is secured by a massy band or hoop of iron. He had his own misgivings and sought refuge in this dangerous remedy.

The "Bucentaur."

Il Bucentaro, the State galley of the ancient republic of Venice, was 100 feet by 21 feet in extreme length and breadth; 168 rowers, four to each oar, were allotted to it from the arsenal, and were disposed in a lower deck; besides these it was manned by a crew of forty mariners. The upper deck was covered with an awning (*tiemo*) of crimson velvet, beneath which were seated the doge and his goodly company. The doge himself was enthroned near the stern, surrounded with

foreign ambassadors, and the senators and great officers of State were disposed on seats running in four rows along the length of the vessel. The date of the original *Bucentaur* is not very clearly ascertained; but, like the famous ship at Athens, although in perpetual flux, the galley of the moment, according to Howell, was ever reputed "to be the self-same vessel still, however often put upon the careen and trimmed. Yet I believe there is not a foot of that timber remaining which it had upon the first dock, having been, as they tell me, so often planked, ribbed, caulked and pieced." The reader may not care to have any elaborate account of the carving and gilding with which it was adorned; and a detail of the marine deities, the sirens, the masques, the fruit, the flowers, the shell-work, the medallions, the cornucopias, the allegorical groups, the winged lions, the birds, the zodiacs, the canopies, the virtues and the liberal arts which were profusely scattered over it on one of its latest repairs by the skill and taste of "Giovanni Adami,

Doratore Veneto." The *Bucentaur* having been conducted on the eve of the feast of Ascension from the arsenal to the piazza, received its splendid passengers. Accompanied by innumerable feluccas and gondolas it passed on to the mouth of the Lido amid the thunder of artillery. On coming in front of the chapel of the arsenal, the rowers, in maritime fashion, saluted an image of the Virgin, and in the meantime the patriarch of Santa Helena, on which island is a convent, awaiting the pomp, was entertained by the monks with a repast of chestnuts and water. As soon as the doge appeared in sight the patriarch embarked with his suite in a small gilded barge in order to meet the procession, and during his passage he blessed the remainder of the water, which was afterwards thrown into the sea. On issuing from the port of Lido, near the mouth of the harbour, the doge dropped a ring into the bosom of the Adriatic, betrothing her by these words:—"We wed thee with this ring in token of our true and perpetual sovereignty." He then re-

LISKEARD CHURCH.

turned to the church of San Nicolo di Lido, and having heard a solemn pontifical mass, re-embarked in the *Bucentaur* and entertained his cortège with a magnificent banquet in the palace. Casaubon, who has been followed by Darù, notices the Venetian custom as reminding him of an offering made to the sea by the Syracusans of an earthen vessel filled with honey, flowers and frankincense.

German Towers.

The campaniles, or belfry towers, of Germany, have quite a distinct character, which seems to be a development of the Anglo-Saxon towers of England, originally carried to Germany by the English missionaries, but never fully developed in England, because the Normans preferred their own towers, which are of a different type. The earliest belfry towers in Germany approach the nearest to the Anglo-Saxon type; long and short work is frequently used, and most of the other characteristic features of that style are found. This type of tower spreads over nearly the whole of the north of Germany and into the German part of Switzerland, where we also find at Roman-Motier a church with other parts besides the tower of Anglo-Saxon character.

Liskeard Church Tower.*

SIR,—As attention has been called to this subject through the medium of your columns, and further as Mr. Norris has written to *The Architect* asking for bona fide criticism, I sincerely hope that such criticism will be given freely. Although anything I can say will, I fear, not be considered by Mr. Norris as free from bias, yet I sincerely trust he will accept my opinion as a bona fide criticism, given solely in the interests of the art I love so well.

From previous correspondence in your columns, it may be remembered that in 1895 I was asked by the committee to report upon the tower, and for this reason, if for no other, I feel now called upon to put plain facts before your readers.

After a careful survey I found that although the tower had been allowed to fall into a deplorable state of decay, there was no reason whatever why, with careful and judicious repair, it should not stand for centuries to come, and I reported accordingly. Now, sir, this being the case—and I unhesitatingly assert that it is without fear of contradiction from any practical man—what are the reasons set forth for the destruction or retention of this tower?

1. Those who advocate its destruction assert that in 1890 a certain Miss Pedler left 1,000*l.* for the purpose of rebuilding the tower, on condition that a new tower was erected at a cost of 3,000*l.* within ten years, otherwise the sum was to be paid over for the benefit of Truro Cathedral, and so be lost for the use of the parish.

2. That because the necessary repairs to the tower would cost a considerable sum, it is better to pull it down and build a new tower.

3. That their intention is to build a tower more "worthy of the church."

I ask any unbiased man whether these reasons are sufficient for destroying one of the most ancient and interesting landmarks in Cornwall.

To deal with these reasons in order:—

1. Because a generous lady, under a mistaken impression, leaves money for a building that necessitates the destruction of an ancient monument, is it therefore to be destroyed? If so, what ancient building is safe? May we be defenced from many such legacies. What, I would ask, is the loss of 1,000*l.* to the parish, compared with the retention of an historic landmark?

2. Is the parish of Liskeard so architecturally interesting that it can afford to lose its chief point of interest, or so poor that it cannot afford to keep its church tower in decent repair?

3. "More worthy of the church." Was ever such a reason more unworthily given? What! destroy a past history reaching back over 600 years for the sake of a brand-new structure, to prevent 1,000*l.* being lost "for the use of the parish."

What, then, are the reasons for the retention of the tower? Sir, in answering the reasons set forth for its destruction, I have almost stated them. The tower is, of its kind, unique in Cornwall. In the main, it is of late Norman date, with the usual interesting additions of later date. It is historically interesting as the oldest building in Liskeard. It is architecturally and archaeologically interesting from its various and curious details. It is quite repairable without detriment to such details.

The fifteenth-century architects, when they rebuilt the nave-

aisles, did not consider it necessary to build a tower "more worthy of the church."

Surely, under the circumstances, the Chancellor has a right to refuse a faculty: if so, surely no momentary local feeling can legally coerce him to grant the same. But I hope the Chancellor will not insist on having the tower rebuilt "as at present," as it can well be repaired as before stated.

In your issue of June 19, you state that I favour the retention of the tower "on the grounds of antiquarian taste." I trust what I have written will show that to me it is much more than a mere matter of taste.

In conclusion, I can only add that my sole aim in writing this is to try and bring it home to others, that they are not only dealing with a thing of local interest. This relic of the past is far more—it is of historical value to Cornwall in particular and to the nation at large, and those who do their best to preserve these ancient landmarks (temporarily committed to their care) will earn the gratitude of all who love to retain the architectural links that bind together the past and present in our churches.—I am, yours faithfully,

GEO. H. FELLOWES PRYNNE.

6 Queen Anne's Gate, Westminster, S.W.:

July 5, 1897.

GENERAL.

The Institute of Painters in Oil-Colours on Monday elected Sir E. J. Poynter, P.R.A., Sir E. Burne-Jones, Mr. G. F. Watts, R.A., Mr. Frank Dicksee, R.A. and Mr. Frederick Sandys as honorary members. Mr. W. Llewellyn, Mr. Julius Olsson, Mr. Niels M. Lund, Mr. W. B. Wollen, R.I., Mr. Alfred Withers and Mr. Robert Noble, A.R.S.A., were elected members.

The New General Hospital, Birmingham, was opened by H.R.H. Princess Christian on Wednesday. The building was designed by Mr. W. Henman, whose aim has been "to adopt the spirit and not the letter of ancient work." Terra-cotta, by Messrs. Doulton, has been largely used. The cost is estimated at 210,000*l.*

A Congress is to be held in Brussels from July 23 to 25 on the subject of "Model Dwellings for Workmen and their Families." M. Beernaert, one of the ministers, will preside.

Mr. Everard Green, "Rouge Dragon" of the Herald's College, has been appointed Vice-President of the Society of Antiquaries.

Mr. George Coffey, whose essays on interlaced ornament have obtained notice, has obtained the appointment of Superintendent of Irish Antiquities in the Dublin Museum.

The Juries will commence their inquiries at the Brussels Exhibition to-day. There are about 800 members, the president being M. Nyssens, the Minister of Industry.

M. Bertone, Grand Prix in Architecture, has sent several able studies of the ruins of Palmyra to the exhibition of "envois" in Paris.

The Works Committee of the London County Council announce that a recent sale by auction of timber unused by the Works Department had resulted in a loss of 674*l.* The cost of the timber was 2,781*l.*, including rent.

Projects have been submitted by several French architects for dealing with the ground in the Rue Jean Goujon, Paris, which was the scene of the recent catastrophe, but as yet the Archbishop of Paris has not given any decision on the subject.

The North-West Gable of Peterborough Cathedral having been restored, the cross surmounting it was fixed in position on Friday last. In the course of the work very few new stones have had to be introduced to take the place of those which were completely ruined by the weather. There are only two new stones in the outside order of the great arch, and with the exception of two small patches the large string-course has been replaced intact. Every stone has been put back into its original position, having been carefully numbered before being taken down.

The New National British Gallery, Millbank, will be opened by H.R.H. the Prince of Wales on July 21.

Mr. Frederick Wheeler, F.R.I.B.A., has removed from 22 Chancery Lane to No. 6 Staple Inn, Holborn, W.C. His Horsham office remains as before.

The Members of the Archaeological Society of Durham and Northumberland on Friday last paid a visit to Brinkburn Priory and Framlington. Morpeth was the base of operations, and the party journeyed from there to Brinkburn by way of Longhorsley, and, through the kind permission of Mrs. Fenwick, the members were able to make a thorough inspection of the historic priory. Framlington was next visited, and here the ancient church, which possesses many features of interest to both architect and antiquary, was examined, and the party returned thence to Morpeth, arriving about six o'clock, after a most agreeable outing.

* For illustration see preceding page.

The Architect.

THE WEEK.

IN our last number we gave an extract from the British Consul's report relating to the proposed harbour at Licata, in Sicily. The British and Italian Finance Syndicate, Limited, write to us and say that the opinion formulated is unfavourable, and is the first notice of the kind that has appeared in either the English or foreign press. Several reports relating to the proposed harbour have been sent to us. One from Mr. A. E. CAREY, M.Inst.C.E., says that Licata is the centre of a large sulphur industry, but it will be "as a coaling centre, and more especially in connection with the vast trade between England and the Continent and India, China and the East that the prospects of the harbour will depend. The sale of the various concessions cannot fail to be a source of large profit." Mr. CAREY adds that the commercial prospect of such an undertaking should, on so small a capital, be extremely good, but his opinion in favour of the project is minimised when it is said that he has not yet had an opportunity to inspect the site of the intended harbour.

A DECISION in one of the Pennsylvanian law courts is interesting for those authorities who insist on certain rates of payment to workmen being defined in the conditions of contract. According to the statute law, public work in Pennsylvania should be given to whoever submitted the lowest tender. But one of the city regulations prescribed that contracts should be monopolised by those contractors who employed members of trades unions and paid union prices. Recently a lowest bidder was refused a contract because he had not a good reputation with the unions for generosity. He brought an action against the city authorities. It was decided by the judge that the Corporation regulation clashed with the law of the land, and defeated the intention of the Legislature, which was to have municipal work executed at the lowest prices. The judge further added that tendering should be free and open to all, and contracts awarded to the lowest responsible bidders without restrictions. Although apparently the decision is in favour of free contracts, the trades authorities are certain to have their will obeyed.

THE London School Board in December, 1895, accepted the tender of Messrs. TREASURE & SON, amounting to 15,186*l.*, for enlarging the Cottenham Road School, Holloway, and also for carrying out various other improvements to the school. These contractors in April last were compelled to forward the following statement of claim for delays:—"A considerable portion of the site (alongside Cottenham Road) was covered with a long row of cottages; according to contract possession was to be given to us in October 1896, but instead of this, part possession was given on or about January 4, 1897, and full possession on or about February 22, 1897. Loss was thus caused by the following, viz.:—1. In preventing any drainage to any part of the site being done, thus causing great loss and delay in completing main building, in completion of w.c.'s, covered sheds, &c., and the site has been more or less flooded with water from roofs, &c. 2. Owing to delay and want of this space for storage we have had to pay the heavy rise in price of bricks for delayed portions of buildings. 3. Owing to the near shoots being closed, we have had to pay 1*s.* 6*d.* per yard additional for removal of all spare earth since December 1. 4. Storage and loss of interest of money, &c., of ironwork, timberwork and various other materials prepared with a view of their being required four months earlier. 5. Owing to the school children being about, the temporary gangways, passages, &c., had to be erected and maintained far in excess of anything contemplated by us when pricing the estimate, and owing to this land not being handed over the space was so limited, materials could only be delivered in comparatively small quantities and causing constant moving by hand from one part of site to another. In addition to this, owing to district surveyor condemning the

usual wooden temporary staircase and compelling the erection of a stone staircase with brick walls, this prevented us taking down the old staircase block and rebuilding new one for several months; this necessitated the erection of new staircase portion as a separate and distinct building to the classrooms. So much has this delayed us that we are only now able to slate in the roof of this portion; this has caused us a very considerable loss in money. We have gone as carefully as possible into the loss to us, and consider that we are fully entitled to the sum of 650*l.*, although this will not cover our actual loss." The works committee have carefully considered the application, and are of opinion that having regard to the fact that possession of a portion of the site was not handed over to the contractors until after the time stipulated in the contract, and that the contractors were undoubtedly put to considerable expense in consequence, and also having regard to other special circumstances in connection with the contract, the payment of a sum of 400*l.* might be made to the contractors for the loss they have sustained, upon the understanding that this payment shall be charged to the cost of site and not to the school building. The claim of the contractors is most moderate, and it will not matter much to them to whose account the money is charged, and the ratepayers will probably be of the same opinion.

It is authoritatively stated that the Marquis of BUTE has decided to erect a Roman Catholic cathedral in Columnshill Street, Rothesay, on the site of the existing chapel. For many years it has been a matter of common report that Lord and Lady BUTE have been desirous of transferring the headquarters of the Roman Catholic diocese of Argyll and the Isles from Oban (where there is a corrugated iron cathedral) to Rothesay, and it may be presumed that the erection of the new building will facilitate the proposed change.

It is to be regretted that a more satisfactory site was not to be obtained for the new National Gallery than that formerly occupied by the prison at Millbank. The ground lies low, and seems unsuited for a building which, if compared with many modern examples, may be described as severely Classical. Like the old temples, the collection of galleries may be described as forming a building of one storey. There is a basement which will be utilised for offices, but the rooms which the public will visit are on the same level, and approached by steps from the outside, as they are about 12 feet above the level of the ground. The entrance leads to an octagon hall lighted by a glass dome. Recesses have been formed for sculpture, and when they are occupied it will form an excellent feature in the building. There are two main galleries measuring 59 feet by 32 feet. One will be assigned to the pictures purchased with money derived from the Chantrey Fund, a great number of them being entitled to be considered as characteristic examples of modern English art. As the gallery is well lighted, we may expect that will have an influence on the trustees, and care will be taken to purchase those pictures alone which can be considered as worthy of becoming national property. As long as there was no fixed local habitation for the pictures it was hardly possible to adopt a rigorous standard, but now that the Millbank Gallery is an accomplished fact the public has a right to expect that chance or favour will not be a factor in the selection. Another room contains the great works which Mr. WATTS has generously handed over to his countrymen. Next we come to the largest gallery, in which by right Mr. TATE's gifts are hung. There are no less than sixty-five pictures, not one of them being obtained by the donor on what would be called economical terms. In another room the pictures transferred from the National Gallery will be found. Mr. SIDNEY J. SMITH can be congratulated on the success of his work. The site was not favourable, but the general verdict of all who saw the rooms on Wednesday is that the galleries are well adapted for the display of the treasures, which can be thoroughly enjoyed by every visitor. From the arrangement it is also possible to enlarge the rooms without causing any inconvenience or closure of the new gallery.

PROPOSED NEW HOUSES OF PARLIAMENT AT SYDNEY.

(FROM OUR NEW SOUTH WALES CORRESPONDENT.)

IT is difficult to imagine a more inconvenient and in every way unsuitable building for legislative purposes than that at present occupied by the Parliament of New South Wales. Its ignoble appearance and utter absence of artistic pretension have long occasioned it to be regarded as an architectural eyesore in the Australian commercial metropolis, and successive Ministries have promised without effect that steps should be taken to remove the unsightly structure and replace it by one more worthy of the high reputation and importance of the colony. Within the last few months, however, Mr. G. H. REED, the colonial Premier, and his Ministerial colleagues decided that the erection of new Houses of Parliament should be included in the list of public works to be undertaken by them. With this object they commissioned Mr. W. L. VERNON, the colonial architect, at present in London, to prepare the necessary plans to be submitted to a parliamentary committee for consideration and approval. As might have been expected, Mr. VERNON'S designs have been subjected to a considerable amount of professional criticism, especially on the part of those desirous of an open competition, but their boldness and comprehensive character have caused them to be regarded with favour by the colonists generally, the only question at issue being that of cost. These designs were prepared by Mr. VERNON, a model on a larger scale than is customary being prepared of that of which we give an illustration, being 1-48th of the actual size of the intended building.

The edifice, which is intended to occupy the site of the present structure and some adjoining buildings, will be 528 feet in length, with a depth of 140 feet across the public lobbies, and of 234 feet from the portico to the projecting library in the centre of the structure. The façade towards the main thoroughfare is broken by the north and south wings and the central portico, all of which are pedimented and connected to each other by colonnaded waists. The portico consists of massive Corinthian columns, strengthened at the angles with piers of severe ashlar masonry, the whole finished with a pediment, the tympanum of which is richly carved with sculpture, and crowned on the apex with a group to represent Wisdom, Purity and Temperance, or some equally appropriate subject. The north and south wings have a solid ashlar appearance broken on the first floor by a recessed loggia with a slightly projecting balcony and solid piers to support the cornice above. The waists are plain in treatment, the chief embellishment being the Ionic colonnades forming the verandahs. Centrally behind the north and south wings rise the octagonal walls and domical roof forming the upper part of each chamber, the crown of each dome being glazed to give light to the legislators below. Centrally behind the portico roof rises the main dome. It is flanked at each angle with four attendant domed towers richly decorated with small columns, the whole, including the small domes, being of stone, connected with each other by a plain ashlar parapet wall. From the enclosure thus formed rises the drum of the main dome, enriched by an Ionic colonnade, which becomes solid when diagonally opposite the flanking towers in order to give the dome a satisfactorily stable appearance. Behind the balustrade of this colonnade rises a minor drum pierced with bull's-eye windows, and from this springs the dome proper, which is deeply ribbed and covered with copper. Above the dome is a gallery slightly bracketed out, and an enriched cupola, inside which it is suggested to place a great arc light, which shall be always shining while the House is sitting, and be extinguished at each adjournment. This dome is, of course, the crowning feature of the whole design, and it is hoped that, should this building be carried out, its construction will not be postponed, as is the case in so many other instances, until the Greek kalends. At each corner of the block of buildings is a square staircase tower carried up considerably above the main roof level, brought from the square to the circle by clusters of Ionic columns, and finished with a conical dome.

The northern and southern façades are kept almost in plain ashlar, with the addition of a central circular bay in

each case. The eastern, like the western, façade is broken by north and south wings and central projection. The wings have pediments supported by Corinthian columns with strong angle-piers of ashlar-work. The library projection has plain ashlar-work below with a circular bay at end, while the dining-room above is treated as solid ashlar for some distance, and the remainder is colonnaded, forming an open loggia. The connecting waists are colonnaded in two storeys, forming wide and spacious verandahs and balconies for use of members. They command an unrivalled view across the harbour, and give an admirable play of light and shade to the façade. The basement throughout will be of rusticated trachyte. As the site slopes downward towards Sydney Harbour a sunk garden is formed on the western side about 6 feet below the level of the main thoroughfare, and finished with an ornamental balustraded wall. This is not only an ornamental and highly effective treatment, but also enables the room on the basement floor to receive ample light and ventilation.

The general disposition of the plan has a right and left wing to the block of buildings to be occupied by the Council and Assembly respectively; a central block, to be occupied by accommodation common to both Houses; and two connecting blocks or waists, to be occupied by public lobbies, offices, &c. The positions of the chambers for both the Council and Assembly were emphasised in the designs, and the great hall is crowned by a dome. On entering the building at the central portico one would pass through the vestibules to the grand hall, which contains the grand staircase up to the first floor, where spacious balconies overlook the entrance floor, and the whole is crowned, as before mentioned, by the main dome. To the right and left of this hall are public lobbies about 76 feet by 35 feet, treated architecturally, and are intended to resemble the French Salles des Pas Perdus where members may meet their friends and constituents without taking them into the sacred precincts of the House. Entering off these lobbies are the post, telegraph, and telephone offices, public rooms for constituents, and staircases to the House galleries. Thus far and no farther may the ordinary average mortal penetrate. The Assembly chamber is planned as a semi-octagon, with a square base, changing above the ceiling to a true octagon or circle, and the roof carried up in this form, and treated as an important feature in the external design. The seats of the chamber are arranged in a semicircular fashion round the table of the House, at the head of which on a raised dais is the Speaker's chair. Special provision has been made for future enlarged requirements for seating without any alteration being necessary to the structural portions of the building. On the right and left of the Speaker are division lobbies for "ayes" and "noes," the division to be recorded at the connecting doorway. Around the whole chamber block is a private corridor, from which on the "aye" side is entered the Ministerial supporters' room, and on the "noes" side the Opposition room and labour members' room. Off this corridor also the Speaker has official quarters, which overlook the harbour, and on the north side are spacious rooms for Ministers.

The Legislative Council chamber is similar in plan but has no division lobbies. The President has the same relative position for his quarters as the Speaker on the Assembly side, and the general lounge and smoking-rooms for the council have a similar position to the Opposition rooms of the Assembly. On the western side rooms are provided for the Governor, and on the southern side is a large reception-room and also rooms for the Vice-president and the Minister in the Upper House. Common to both Houses in the central block is a large and spacious library, entering off which are smaller special libraries and a writing-room, and by means of a special staircase direct access is provided to a large archives library in basement. Immediately above the general library is located the members' dining-room, about 25 feet of the length being arranged as an open-air loggia, where members may dine in hot weather, and which they could use as a lounging café throughout the year. To the right and left of the dining-room are suites of committee-rooms for the use of both Houses, and the chairmen of committees have their official rooms immediately over those of the President and Speaker respectively. The north wing facing Macquarie Street is occupied by the

Premier's under-secretaries, and one includes Ministers' room, while the remainder of the accommodation on this floor is given to Parliamentary officials and to "Hansard" and the daily press. On the second floor there are extra rooms for the press and the Parliamentary officials, and also for kitchen and general service, as well as stewards' quarters.

In the basement under each chamber is ample storage for records; under the grand hall is a crypt lighted from the floor of hall; under the council public library is space for machinery for heating, ventilation and lighting; under the correspondents' assembly lobby are muniment and strong rooms; under the President's and Speaker's quarters there are official quarters for librarian and serjeant-at-arms respectively; and there are also quarters for a caretaker for each House. Situated next to the serjeant-at-arms' rooms and entered from the members' terrace overlooking the Domain (the St. James's Park of Sydney) is a tea-room where members may entertain their friends or constituents. All the rooms overlooking the main thoroughfare are devoted to offices for Parliamentary officials, as well as some additional public-rooms for constituents. There are three passenger lifts and one for service, and there is also ample staircase accommodation. The estimated cost is 500,000/. Should the New South Wales Parliament endorse the Government project the colony will possess the most magnificent public building in the southern hemisphere.

SIR HENRY RAE BURN, R.A.

THE sale of nine portraits by Sir HENRY RAE BURN at excellent prices on Saturday last by Messrs. CHRISTIE was an event in the auction market. It was, as it were, the formal admission of another artist to the favours of amateurs, for henceforth it may be assumed that RAE BURN's portraits will have their special admirers, who will be willing to pay liberally for the privilege of possessing examples. Most of the portraits were of members of the family of FRASER, who were unknown to Englishmen or to fame, and yet the prices varied from 330 to 640 guineas. The name of *A. F. Tytler, Lord Woodhouselee*, is not altogether unfamiliar, for he wrote books about history, taxation and the principles of translation. He was also a Scottish judge and lord of judicatory, but his portrait was sold for 215 guineas, whilst one of his wife was valued at 1,250 guineas. It would, therefore, appear that the quality of RAE BURN's work rather than the subjects have had influence with dealers, and on that account the future value of his portraits is not unlikely to increase.

Fortune, in her dealings with pictures, is whimsical; but it is not often so much merit as is apparent in RAE BURN's portraits characterises the productions of a new competitor in the St. James's Street rooms. That peculiar feeling of being at ease before a work of a master who never goes beyond his powers always arises on seeing the Edinburgh artist's men and women. There seems to be no laborious effort, for the heads are suggestive of a few bold strokes. But they stand out from the background as if they were reliefs. In fact, they were at one time considered to be too prominent, for some of his admirers advised RAE BURN to alter his backgrounds in order that there might be a less marked contrast with the figures. It was not understood that he wished to exhibit racial peculiarities, and neither WATSON GORDON, CHALMERS, nor any of the living portraitists has succeeded so well in the representation of the strongly marked countenances of the North. RAE BURN was compelled to pay a price for his success. He rarely was able to do justice to the features of the Scottish maiden on his canvas, and although he fancied that Sir THOMAS LAWRENCE was not altogether unselfish in advising him against a removal to London, we believe that with English subjects RAE BURN's success would be less manifest.

RAE BURN could not be a cosmopolitan painter. He was a Scotsman to the core, and nature prevailed over him in the selection of subjects and in other ways. His style was his own. There was no artist who was more of an admirer of REYNOLDS's works, and under the guidance of GAVIN HAMILTON and BYERS he endeavoured to transform himself into one of the Renaissance masters, but his endowments

were too strong to submit to outer influences. In youth and age his originality found expression. If it were not for his innate power he would never have painted portraits. He belonged to that middle class that assess utility by the amount of money gained, and therefore prefer industrial or mercantile pursuits. His father was a manufacturer at Stockbridge, which in 1756, when RAE BURN was born, was a suburb of Edinburgh. But young RAE BURN was only six when he was orphaned. He was not a brilliant boy, and the Heriot masters did not prophesy a brilliant future for him. He only showed skill when making drawings and caricatures for the amusement of his fellows, and as a rule the judicious generally grieve over displays of that sort.

The spirit of the family inspired RAE BURN when it was necessary for him to select an occupation. He became a goldsmith's apprentice. In one of the old Italian cities a choice of that kind would be taken as evidence of artistic ability. To the son of the Stockbridge manufacturer the craft was only an expeditious mode of winning gold. With a little experience of the workshop he was disillusionised. RAE BURN was no model apprentice whose worth was to be rewarded with the hand of the goldsmith's daughter. Apprentices and journeymen were glad to have among them a youth who was delighted to caricature the whole establishment for their amusement. But those hours brought no profit to the master. We imagine that RAE BURN was not more successful as a messenger. He was too fond of gazing at print shops and booksellers' windows where engraved portraits were to be seen. But somehow the thought struck him that caricatures were becoming monotonous, and as a change he tried to imitate the miniatures which were then to be seen in glass cases as baits to those who were ambitious to be immortalised. The goldsmith was kindly but shrewd. He recognised that the untaught apprentice possessed talent, but he could not be blind to the fact that the time which by indenture belonged to him was wasted over attempts at portraiture, and that it was hopeless to expect much assistance from his apprentice. The fate of the lad was also to be considered. It may not be enjoined in long or short catechisms, but in no country in the world is there a stronger sense of the duty which belongs to age to foster the young, and to it Scotland is indebted for much of her power. Accordingly, RAE BURN's master brought him and his drawings to a painter named MARTIN. He also was inspired by the belief that it was obligatory to help a tyro. MARTIN not only gave advice but encouraged RAE BURN to pursue painting. As a consequence the young miniaturist was emboldened and produced better work. Several people also gave him commissions, for the prices of his likenesses were moderate. The goldsmith, realising that he must not raise obstacles to a career that was likely to be successful, agreed to cancel the indentures on the payment of reasonable compensation.

To an artist with so much largeness of style the painting of miniatures was like imposing fetters on his hands. It is not wonderful that when he decided to give freedom to his power he should rush to the opposite extreme and endeavour to paint life-size figures. He was unacquainted with the elements of the practice of painting in oils. The preparation of the canvas, the mixing of colours, the laying-on of paints had all to be discovered by means of a succession of failures. But he was young and enthusiastic. After many trials RAE BURN succeeded. He had hardly passed his twentieth year when he was admitted to be the most popular portrait-painter in Edinburgh. Success did not spoil him. RAE BURN had a misgiving that, owing to his want of instruction, his pictures were not deserving of the praise which was awarded to him. To gain knowledge he resolved to visit REYNOLDS, who then was considered to be supreme. But the President was never disposed to part with the knowledge he had acquired about the technique of his art, although he must have perceived that as RAE BURN was without the aid of a HUDSON to guide his first steps, the simplest hints might have their use. As usual, REYNOLDS recommended a course of study in Rome and especially of the works of MICHEL ANGELO. If he was not disposed to part with any of his studio secrets at least he was willing to be generous with money, for he proffered RAE BURN whatever sum he might consider necessary for his Italian studies. But the Scotsman was not needy. He

had probably contrived to save a part of his income, and a short time before his visit to London he had married a wealthy lady.

RAEBURN next spent a couple of years in Rome. It is always difficult to estimate the growth of the intellect, and he could not see every day a multitude of noble works without an expansion of his artistic powers. But what he most valued as a result of his life in Rome was the advice he received about avoiding any copying from memory, but to insist on having everything he represented, however small, before his eyes. He attached more importance to the counsel than most painters, and the almost realistic character of his works, although free from an excess of detail, is explained by its adoption.

RAEBURN was in his thirty-first year when he returned to Edinburgh and opened a studio in George Street. He was most systematic in his art. At nine o'clock every day he was ready to receive subjects. A sitting lasted an hour and a half or two hours, and he therefore required from six to eight hours for painting a head. Three or four subjects a day he considered sufficient. He never sketched his heads with crayons, but boldly began with colours. His hand was so steady he had no need of a maulstick or other rest. It is remarkable that he kept no list of his portraits, and in consequence there is a danger that when the demand for them increases, as is now likely, works will be ascribed to him which were never touched by his fingers. Of his manner of painting the following account was given by a sitter:—"He spoke a few words to me in his usual brief and kindly way—evidently to put me into an agreeable mood; and then having placed me in a chair on a platform at the end of his painting-room in the posture required, set up his easel beside me with the canvas ready to receive the colour. When he saw all was right, he took his palette and his brush, retreated back step by step, with his face towards me, till he was nigh the other end of his room; he stood and studied for a minute more, then came up to the canvas, and without looking at me, wrought upon it with colour for some time. Having done this, he retreated in the same manner, studied my looks at that distance for about another minute, then came hastily up to the canvas and painted a few minutes more. I had sat to other artists; their way was quite different—they made an outline carefully in chalk, measured it with compasses, placed the canvas close to me, and looking me almost without ceasing in the face, proceeded to fill up the outline with colour. They succeeded best in the minute detail—RAEBURN best in the general result of the expression; they obtained by means of a multitude of little touches what he found by broader masses; they gave more of the man—he gave most of the mind."

It was the good fortune of RAEBURN to be commissioned to paint the portraits of the most eminent of his contemporaries in Scotland. He was the national painter, and the representatives of literature, law, academicism, theology can be recalled by his canvases. They form a memorable collection. The chiefs of old families, and, in fact, all who had any pretension to be considered as above the crowd, found their way to his studio. In 1815 he was elected a Royal Academician, but he avoided London, and Englishmen were not disposed to venture as far as Edinburgh in order to find a portrait-painter. As years advanced there was no decline in his skill, which seemed to correspond with his health, that was always unattacked. But a few days' illness at last was fatal to him. RAEBURN died on July 8, 1823, the day on which he was nominated to the office of King's limner and painter in Scotland, with all the fees, profits, salaries, rights, privileges and advantages thereto belonging.

CANTERBURY CATHEDRAL.—III.

THERE are no artists who are so quickly forgotten as architects. A picture or statue in one of their buildings may bring fame to the creator, but about the designer of the building which it helps to adorn and who probably inspired it, few care to inquire. With so many examples of the modern neglect of architects, we need not be surprised nor angered when we find the names of the designers of Mediaeval cathedrals and churches are not to

be traced. In fact, modern ingenuity has devised a theory to excuse the indifference to men who by their buildings have conferred honour on many cities and towns. The architects are supposed to have been so modest and self-sacrificing they considered it sinful to have their names associated with an ecclesiastical building. Exalted virtue of that kind seems to be ill adapted to mortals, and especially to artists. It is probable they were under the delusion that somehow their names would be remembered among the people who rejoiced in their buildings, but the compilers of records and chronicles preferred to inscribe the names of other men in their manuscripts. Canterbury is an exception to the almost universal indifference. We are enabled to recall two at least among the numerous architects who helped to create the cathedral. For that favour to the art we are indebted to Brother GERVASE, who was one of the monks that were scared almost to death by the murder of BECKET. He was a witness of the conflagration of the cathedral two years afterwards, which he attributed to "the just but occult judgment of God," and he was among those who considered themselves as exiles because there was no choir left in which they could recite their offices, and they were compelled to pray and chant for five years in the nave, "separated from the people only by a low wall." The object of his narrative was, of course, to excite the sympathy of the Christ Church monks in future ages about the sufferings of GERVASE and his companions, who were compelled to mix with the laity through the destruction of their "paradise of pleasures." But to attain his purpose he considered it was necessary to be more precise in details than is usual with monastic annalists when describing things made of wood or stone. His whole tract "On the Burning and Repair of the Church of Canterbury" deserves to be included in every description of the cathedral, but our readers will be likely to consider that the part relating to the rebuilding of the choir, which is the subject of one of our illustrations, will be sufficient for the present:—

The brotherhood sought counsel as to how and in what manner the burnt church might be repaired, but without success; for the columns of the church, commonly termed the pillars, were exceedingly weakened by the heat of the fire, and were scaling in pieces and hardly able to stand, so that they frightened even the wisest out of their wits. French and English artificers were therefore summoned, but even these differed in opinion. On the one hand, some undertook to repair the aforesaid columns without mischief to the walls above. On the other hand, there were some who asserted that the whole church must be pulled down if the monks wished to exist in safety. This opinion, true as it was, excruciated the monks with grief, and no wonder, for how could they hope that so great a work should be completed in their days by any human ingenuity?

However, amongst the other workmen there had come a certain William of Sens, a man astute and ready, and as a workman most skilful both in wood and stone. Him, therefore, they retained on account of his lively genius and good reputation, and dismissed the others. And to him and to the providence of God was the execution of the work committed. And he, residing many days with the monks and carefully surveying the burnt walls in their upper and lower parts, within and without, did yet for some time conceal what he found necessary to be done, lest the truth should kill them in their present state of pusillanimity.

But he went on preparing all things that were needful for the work, either of himself or by the agency of others. And when he found that the monks began to be somewhat comforted he ventured to confess that the pillars rent with the fire, and all that they supported, must be destroyed if the monks wished to have a safe and excellent building. At length they agreed, being convinced by reason, and wishing to have the work as good as he promised, and, above all things, to live in security. Thus they consented patiently, if not willingly, to the destruction of the choir.

And now he addressed himself to the procuring of stone from beyond sea. He constructed ingenious machines for loading and unloading ships, and for drawing cement and stones. He delivered moulds for shaping the stones to the sculptors who were assembled, and diligently prepared other things of the same kind. The choir, thus condemned to destruction, was pulled down, and nothing else was done in this year. In the following year, that is, after the feast of St. Bertin (September 5, 1175), before the winter, he erected four pillars, that is, two on each side, and after the winter two more were placed, so that on each side were three in order, upon which and upon the exterior wall of the aisles he framed seemly

arches and a vault, that is, three *claves* on each side. I put *clavis* for the whole *ciborium*, because the *clavis* placed in the middle locks up and binds together the parts which converge to it from every side. With these works the second year was occupied.

In the third year he placed two pillars on each side, the two extreme ones of which he decorated with marble columns placed around them, and because at that place the choir and crosses were to meet, he constituted these principal pillars. To which, having added the keystones and vault, he intermingled the lower triforium from the great tower to the aforesaid pillars—that is, as far as the cross—with many marble columns. Over which he adjusted another triforium of other materials, and also the upper windows. And in the next place, three *claves* of the great vault from the tower, namely, as far as the crosses. All which things appeared to us and to all who saw them, incomparable and most worthy of praise. And at so glorious a beginning we rejoiced and conceived good hopes of the end, and provided for the acceleration of the work with diligence and spirit. Thus was the third year occupied and the beginning of the fourth.

In the summer of which (the fourth year), commencing with the cross, he erected ten pillars, that is, on each side five. Of which the two first were ornamented with marble columns to correspond with the other two principal ones. Upon these ten he placed the arches and vaults. And having, in the next place, completed on both sides the triforia and upper windows, he was, at the beginning of the fifth year, in the act of preparing with machines for the turning of the great vault, when suddenly the beams broke under his feet and he fell to the ground, stones and timbers accompanying his fall from the height of the capitals of the upper vault, that is to say, of 50 feet. Thus sorely bruised by the blows from the beams and stones, he was rendered helpless alike to himself and for the work, but no other person than himself was in the least injured. Against the master only was this vengeance of God or spite of the devil directed.

The master, thus hurt, remained in his bed for some time under medical care in expectation of recovering, but was deceived in this hope, for his health amended not. Nevertheless, as the winter approached, and it was necessary to finish the upper vault, he gave charge of the work to a certain ingenious and industrious monk, who was the overseer of the masons—an appointment whence much envy and malice arose, because it made this young man appear more skilful than richer and more powerful ones. But the master, reclining in bed, commanded all things that should be done in order. And thus was completed the ciborium between the four principal pillars. In the keystone of this ciborium the choir and crosses seem, as it were, to meet. Two ciboria on each side were formed before the winter, when heavy rains beginning stopped the work. In these operations the fourth year was occupied, and the beginning of the fifth. But on the eighth day from the said fourth year, on the idus of September, there happened an eclipse of the sun at about the sixth hour, and before the master's accident.

And the master, perceiving that he derived no benefit from the physicians, gave up the work, and, crossing the sea, returned to his home in France. And another succeeded him in the charge of the works—William by name, English by nation, small in body, but in workmanship of many kinds acute and honest. He in the summer of the fifth year finished the cross on each side, that is, the south and the north, and turned the ciborium which is above the great altar, which the rains of the previous year had hindered, although all was prepared. Moreover, he laid the foundation for the enlargement of the church at the eastern part, because a chapel of St. Thomas was to be built there.

For this was the place assigned to him, namely, the chapel of the Holy Trinity, where he celebrated his first mass, where he was wont to prostrate himself with tears and prayers, under whose crypt for so many years he was buried, where God for his merits had performed so many miracles, where poor and rich, kings and princes, had worshipped him, and whence the sound of his praises had gone forth into all lands.

The master William began, on account of these foundations, to dig in the cemetery of the monks, from whence he was compelled to disturb the bones of many holy monks. These were carefully collected and deposited in a large trench, in that corner which is between the chapel and the south side of the infirmary house. Having, therefore, formed a most substantial foundation for the exterior wall with stone and cement, he erected the wall of the crypt as high as the bases of the windows. Thus was the fifth year employed and the beginning of the sixth.

In the beginning of the sixth year from the fire and at the time when the works were resumed, the monks were seized with a violent longing to prepare the choir so that they might enter it at the coming Easter. And the master perceiving their desires set himself manfully to work to satisfy the wishes of the convent. He constructed with all diligence the wall which encloses the choir and presbytery. He erected the three altars

of the presbytery. He carefully prepared a resting-place for St. Dunstan and St. Elfege. A wooden wall to keep out the weather was set up transversely between the penultimate pillars at the eastern part, and had three glass windows in it. The choir, thus hardly completed even with the greatest labour and diligence, the monks were resolved to enter on Easter Eve with the new fire. As all that was required could not be fully performed on the Saturday because of the solemnities of that sacred day, it became necessary that our holy fathers and patrons, St. Dunstan and St. Elfege, the co-exiles of the monks, should be transferred to the new choir beforehand. Prior Alan, therefore, taking with him nine of the brethren of the church in whom he could trust, went by night to the tombs of the saints that he might not be incommoded by a crowd, and having locked the doors of the church, he commanded the stonework that enclosed them to be taken down. On the morrow, however, when this translation became known to the whole convent, they were exceedingly astonished and indignant that it should have been done without their consent, for they had intended that the translation of the fathers should have been performed with great and devout solemnity.

By the intervention of Archbishop RICHARD and other authorities peace was restored among the monks. It was one of the most serious duties to transfer relics, and CARLYLE has described in "Past and Present" the remorse of Abbot SAMSON for having acted like the Canterbury prior. As was arranged, the community were able to enter the choir on Easter Sunday in the year 1180, after an absence of five years, seven months and thirteen days. The Archbishop began the Te Deum, and amidst the ringing of bells "the convent took up the song with great joy, and shedding sweet tears, they praised God with voice and heart for all His benefits."

The narrative of GERVASE, it will be seen, relates to a period when laymen were recognised as architects. Evidently WILLIAM OF SENS was one. If he were a monk he could not keep his own counsel about the extensive demolition which was contemplated by him. In those days English quarries were not properly worked, and WILLIAM OF SENS was obliged to have stones brought over from Caen. The transit of materials was also a difficulty, and hence he was compelled to construct machines for loading and unloading, as well as carts that would withstand the shocks received in passing along irregular tracks. The masons could not be trusted to shape the stones without moulds. An architect's office in the eleventh century plainly could not be filled by an amateur. It is not easy to give a correct notion of vaulting without the aid of diagrams, and GERVASE was puzzled in describing the parts, and some of the terms he employs no longer retain the same signification. We suppose he dare not approach WILLIAM OF SENS for explanations. The architect evidently directed all the important operations on the spot, and his accident suggests that he took up a position of danger from which his assistants recoiled. WILLIAM must have possessed models or drawings, otherwise he could hardly have directed operations and explained procedure whilst lying in bed. It is also evident that he could appoint a deputy. At Canterbury the overseer of the masons was selected; he was a monk, and his appointment excited the envy of his brethren. Whether he was the English WILLIAM who was to be the successor of WILLIAM OF SENS cannot be determined, but a man who was able to undertake the superintendence at a critical period would apparently be competent to carry on the works which were required for the completion of the scheme, the principal being those of the Trinity Chapel and corona.

STREET LIGHTING BY ELECTRICITY.

THREE papers were read on this subject at the recent annual meeting of the Municipal Electrical Association, by Mr. H. L. P. BOOT, borough electrical engineer, Tunbridge Wells; Mr. C. D. TAITE, borough electrical engineer, Southport, and Mr. S. E. FEDDEN, electricity mains superintendent, Edinburgh, each dealing more particularly with a special point.

Mr. BOOT goes into the capital cost of the various systems of lighting, Mr. TAITE the use of "rectifiers" for obtaining continuous currents from high-tension alternating mains: in fact, Mr. BOOT and Mr. TAITE confine themselves to the

case of a central station working by means of alternating currents.

The points in these papers which will be of interest to borough surveyors, such as the candle-power and arrangement of lamps, will be dealt with more fully than those of interest to central station engineers.

Dealing first with Mr. Boor's paper. He speaks of the difficulties confronting the municipal electrical engineer in connection with the supply of electrical energy in towns where considerable opposition is experienced from local interests. He says that people are not satisfied by being given the same amount of light in another form, although it may put money into their own pockets instead of into a rival company's. He further says that "it is exceedingly difficult to convince councillors, and the public generally, that, by lighting their streets in a manner which is worthy of the nineteenth century, they are decreasing crime, assisting in maintaining law and order, and educating the people one step further in civilisation. . . . There is, however, the cry of the so-called 'economist,' whose main object seems to be to keep down the rates at the expense of efficiency." This paragraph should be taken to heart by all municipal engineers and town councillors, as we are sure that in these matters cost is too often considered first and efficiency afterwards. The author's aim is to endeavour to light the streets with electricity in preference to gas, at the same cost, and he says this can be done if the public are satisfied with the same amount of light.

The author is quite right when he emphasises the importance of carrying out a liberal scheme of public lighting from the very commencement of supply, as it acts as the best of advertisements, and also it costs less to lay the cables with the others than to extend afterwards. This point is of great importance, and it will be noted on examining the results of central station working, especially in provincial towns, that a good system of public lighting usually accompanies a successful undertaking.

The portion dealing with arc lamps, &c., is not as clear or correct as it might be. The author discusses the distances apart of arc lamps and actually goes so far as to give a table of towns and extract an average distance. The distance (100 yards as a max.) which he says should never be exceeded is, of course, perfectly useless, except as an extremely rough figure. The author says that "from the table it will be seen that few towns seem to be of the same opinion as to the correct distance." This is easily understood, because there is no fixed correct distance. The distance apart and height of arc lamps, or any lamps, depends upon the kind of street (whether crooked or straight, wide or narrow), the candle-power of each lamp, the illumination required and several other points. Then with regard to arc *v.* incandescent lighting the author goes wrong, or at least does not answer his question, "When and where should arc lamps be used?" This subject must be studied scientifically for every case, and until this is done there will be great differences in practice and often failures, owing to arcs being used when incandescent lamps would be better, and *vice versa*. Account must be taken of the maximum and minimum illuminations required, and of the smallest arc lamp which will work satisfactorily, together with cost of trimming and capital expenditure. Note must be taken of the different distribution of light from the two sources, and the subject is one which cannot be lightly dismissed. The most important factor is the limitation in power of arc lamps. The small arc lamps will replace the larger incandescent, as their steadiness and time of burning without attention increases. To attempt to fix the distance between the posts irrespective of the circumstances is absurd. The author goes further, and fixes the best power of an arc lamp. He says:—"The author's experience is that the best effect for the money can be obtained by using rectified arc lamps of 500 watts, or alternating arc lamps taking 270 watts." The author does not state why he thinks arc lamps of a particular size best; surely circumstances will determine the best power.

The author then goes on to describe the different systems of arc-lighting when supplied from an alternating current central station. As these systems chiefly concern electrical engineers a short summary only will be given:—

A. By separate plant, *i.e.* by putting down a separate engine and dynamo.

B. By a motor generator, *i.e.* an alternating current motor driving a continuous current dynamo.

C. By rectifiers, machines which cut up the alternating current, reversing one-half of the cycle and give an unsteady continuous current.

D. Using the same plant for public and private lighting, and probably the same mains.

The capital outlay with "C" the author reckons out at 1,570*l.* 11*s.* with 25 lamps, and the annual cost as 47*l.* 17*s.* 1*d.* per annum. With "D" the capital outlay is 898*l.* 7*s.*, and the cost of upkeep 457*l.* 10*s.* per annum. There are no figures given for the other methods. Mr. Boor's preference for the rectified arc is not borne out by the figures given, as they cost more to run and more to erect in the first instance. While on the subject of rectified arcs it may be of interest to collect the opinions of the three authors on the matter.

Mr. Boor gives the advantages of "C" as efficiency of arc lamp; the small attention required by the lamps (owing to the vibration); the capital outlay is not so heavy as with a separate plant or motor generator, and the repairs to the rectifier are very small; the current is kept perfectly constant by the constant current transformer; they run off the ordinary plant and keep it loaded, and very little attention is required. The only disadvantage mentioned is that when the motor is new, and when the load is coming on rapidly, the rectifying commutator is liable to flash over (*i.e.* short circuit, putting the lights out) because the synchronous motors get out of step.

Mr. TAITE says that the efficiency, small upkeep and minimum of floor-space are the causes that have led to its adoption. The efficiency is over 93 per cent. at full load and 87.4 per cent. at half load. The upkeep is low, and attendance very small. The disadvantages are that considerable care is required with the commutators, and that there must be no irregularity in the running of the engines.

Mr. FEDDEN says that the "Edinburgh experience of rectifiers is that they are very tricky, because when one goes wrong or a fuse blows, the others which are running are liable to follow suit, run out of phase, flash over, causing the lamps to pump, and eventually stop. It is then necessary either to switch all the lamps out or to run alternating currents through them, with the result that either the town is in darkness or that the lamps are damaged." Mr. FEDDEN says that it is impossible to run the rectifiers and incandescent lamps from the same circuit owing to the unsteadiness. He thus bears out Mr. TAITE's statement that extremely steady running of the engines is necessary.

Returning to Mr. Boor's paper, a point which is worth consideration is the turning on and off of the public lamps. At Tunbridge Wells the policemen have been provided with special keys, with which they turn the lamps on and off at the proper time as they pass them on their beat. This is the means of saving the expense of lamplighters.

In Mr. FEDDEN's paper there are several interesting points, and the placing of arc lamps is again discussed. The author's opinion is that the effect is best when all lamps are suspended at the same height from the ground; but he mentions the continental practice of putting lamps at various heights, and asks for the views of the meeting on these points. We should think that where the streets are level, where lamps of the same size are used, and where the same illuminations are required the lamps should be at a fixed height and distance apart; but that where the illuminations vary, owing to varying importance of the streets, and where the size of lamp is fixed, as it usually is, then the height and distances apart should be greater, as less illumination will suffice.

Mention is made of the splendid lighting of Prince's Street, Edinburgh, to Calton Hill.

The running of lamps in series across the low-tension mains is very sensibly recommended as being far superior to rectifiers, &c. The author mentions running 40 or 50 alternating arc lamps direct from a 2,000 or 3,000 volt alternator, and says that the only remaining point is to get a good alternating arc lamp.

A point in connection with the use of tower ladders for trimming the lamps is that they are very unmanageable in windy weather, as many as five or six men being often required to hold them up. The ladders are also a great

source of expense and trouble, owing to their falling to pieces rapidly through the jolting on the granite setts.

The benefits of arc lighting enumerated by Mr. FEDDEN are that :—(1) The load factor of the central station is considerably increased owing to the long hours of burning. (2) It gives a good load between, say, 12 P.M. and 6 A.M., when otherwise none would be on at all. (3) It has most decidedly reduced crime in the densely populated districts where it has been specially used. (4) It acts as the best advertisement. (5) It reduces station costs in every direction. The author exhibits curves showing the improvements in load and load factors due to the arc lighting. In conclusion, it must be said that Mr. FEDDEN's paper stands out as combining correctness with very useful information, and a record of experience in one of the most successful and largest of our central stations in connection with arc lighting.

The Old Church of St. Pierre on Montmartre, by the efforts of the archæologists, has been saved from demolition. It is to be repaired at the joint expense of the city of Paris and the State.

STATUARY FOR THE NEW MARKETS AT SYDNEY.

SEVERAL months ago the Sydney Municipal Council offered a series of prizes for a group of statuary for the main entrance to the new markets now approaching completion in Sydney. There were three competitors, each of whom submitted a model in clay, together with the prices required for the reproduction of the same in marble, bronze, or freestone. Ultimately a group designed by Mr. William P. McIntosh, of Sydney, was accepted, the sculptor undertaking to make two replicas in marble for the sum of 3,150/., one for each principal entrance to the markets. The successful design represents a group of three figures. Standing upon a raised pedestal in the centre is a lightly-draped female figure representing the controlling power or guardian genius of the city, with a sword and scales of "Justice" in one hand and a scroll of "Wisdom" in the other. On her head is a civic cross and waratah wreath, and at her feet a shield bearing the city crest. On her right hand is seated a semi-nude muscular male figure representing "Labour," with the approved symbols grouped around him, viz. the wheat, ram, fruit and beehive. On the other side a corresponding male figure representing "Commerce" and "Exchange," with a ship by his side in full sail. His left hand holds a bag of money, while his right rests upon a ledger-book.

NOTES AND COMMENTS.

ACCORDING to the arrangements of the Government the Tate Gallery will to some extent correspond with the Luxembourg Gallery. In the latter the majority of the works are by living artists, whilst in the Tate Gallery the general principle of selection adopted by the trustees and director has been to accept all works by British painters born after 1790. Accordingly, no less than ninety-seven pictures have been transferred from Trafalgar Square to Milbank; but certain exceptions have been made to this rule. Almost all the pictures by Sir EDWIN LANDSEER have been retained in the National Gallery, and, on the other hand, a few small paintings by CONSTABLE (born 1776) and a few examples of WILKIE (born 1785) have been removed to the Tate Gallery. All pictures of the earlier British school, including the works of HOGARTH, WILSON, REYNOLDS, GAINSBOROUGH, MORLAND, COPLEY, ROMNEY, STOTHARD, OPIE, CROME, LAWRENCE, TURNER and others, will remain in the National Gallery and have been hung in the western wing of the building. The Tate Gallery will also contain not only Mr. TATE's own gift of modern British pictures, but also the modern British pictures and sculptures bought by the Chantrey trustees out of their trust fund and at present housed at South Kensington. After a time it is not unlikely the advantage of restricting the wall space to the exhibition of works by living painters will be recognised, and then pictures which were produced by artists who were born in the last century will have to be returned to the National Gallery.

PARIS has somehow contrived to preserve some examples of Mediæval architecture, and there is no doubt they increase the charm of the street views, but the requirements of modern business seem to be a merciless power which will not spare the most venerable object if it is supposed to be an obstacle. To it the thirteenth-century house at the angle of the Rue des Prêcheurs and the Rue Saint Denis is about to be sacrificed. One of the features of the building was an immense beam of oak, on which a tree of JESSE was carved. It was unlike the ordinary Mediæval examples, for the patriarchs were represented by Dominicans. It is to be hoped that a piece of woodwork which has stood so long will be secured for one of the archæological museums.

THERE are a great many memorials of the dead which could be removed with advantage from great churches, but an exception should be made in favour of those which were commissioned by the State out of gratitude. They correspond with peerages and baronetcies. If that view were recognised by the Dean and Chapter of St. Paul's, there would have been no need to excite commotion by a proposal to remove the Burges monument. It was erected by order of Parliament as a recognition of the heroic effort of RICHARD RUNDLE BURGESS to break through the Dutch fleet at Camperdown in 1797. The space was to be utilised for the monument of Lord LEIGHTON, but would the late president have approved of the eviction? Lord CHARLES BERESFORD, in a letter on the subject, wrote:—"Lord LEIGHTON was a personal friend of my own, but I have yet to learn that he was the sort of man who would have wished to usurp the place of anyone, or that he would have even admitted that an artist, however distinguished, takes precedence in the nation's memory of those heroes to whom the existence of our Empire is due. I rather think from what I knew of Lord LEIGHTON's character, that had such an hypothesis been presented to him in his lifetime his answer would have been much like that of Her Gracious Majesty the QUEEN, who, it is reported, when it was suggested to her that Queen ANNE's statue should be moved to make room for one of herself, replied, 'Certainly not; why, you would be proposing to move mine next.'" The Burges monument may not be in the highest style of art, but if critical rules are applied, very few statues would be allowed to remain in St. Paul's. It is difficult to interfere with the determination of an English dean, but, owing it is said to the mediation of the Prince of WALES, the Burges monument is to be allowed to remain in the position it has occupied for nearly a century.

THE prejudice against South Kensington officials is so general the select committee could hardly be free from its influence, and it was, moreover, not likely to be diminished by the evidence which was given. It inspired the voting, which has led to the resignation of Sir JOHN GORST as chairman. To obtain a copy of a paper which was offered as evidence without the formal approval of the chairman is an irregularity according to Parliamentary procedure, but if the deed were done by other officials it would not be an unpardonable sin. South Kensington must be suspected to commit more than oversights. Sir JOHN GORST is a man of honour who would not tolerate the least deviation from the prescribed rules, and it was absurd to make a scapegoat of him. His resignation of the office is likely to delay the decisions of the committee and to deprive the conclusions of much of their value.

ILLUSTRATIONS.

THE CHOIR, CANTERBURY CATHEDRAL.

ON another page an account is given of the erection of the new choir after the destruction of CONRAD's choir. It is difficult to discriminate between the parts erected by the two WILLIAMS. Professor WILLIS observes:—"In a new building the lower part is necessarily erected first, and the works proceed regularly upwards, but in a case of this kind there can be little doubt that the essential part, namely, the raising of the clerestory walls and the erection of the vault, would be first done, and then the decoration of the lower part, which consisted merely of a new lining to the old walls, would be proceeded with. But as GERVASE has distinctly recorded the vaults of these transepts as the last works of the Frenchman, and the finishings of the transepts as the first works of the Englishman, a very probable case is made out in favour of the introduction of the round abacus by him, inasmuch as this is a new feature in the work, and as such, very likely to have been introduced by a new architect; everywhere else, however, he has adhered to the square abacus of his predecessor, excepting, as before said, in the crypt, where he had none of the previous work to guide him. However, it must be very difficult to judge of the unfettered style even of WILLIAM OF SENS, because in every part of his work the retention of the old Norman portions evidently cramps and governs his composition." An account is also given elsewhere of the introduction of new stalls in the choir as substitutes for those which were set up at the beginning of the eighteenth century.

ST. MICHAEL'S, OR WARRIORS' CHAPEL, CANTERBURY.

THE old chapel of St. Michael, in the south transept of Canterbury Cathedral, was replaced in the fourteenth or fifteenth century by another, which we illustrate, and which almost corresponds in position with the lady chapel adjoining the Martyrdom on the northern side. To whom the credit for so beautiful an example of Perpendicular should be given is not recorded. Professor WILLIS describes the roof as "a complex lierne vault of an unusual pattern, but resembling that of the north transept of Gloucester Cathedral, which dates from 1367 to 1372." In the middle of the chapel is a monument erected by MARGARET HOLLAND to the memory of her two husbands, viz. the Earl of SOMERSET, who died in 1410, and the Duke of CLARENCE, who died in 1420. As she died in 1437, the monument was erected between 1420 and 1437. The chapel was, therefore, in existence at that time.

Over the chapel is a vaulted room, on the keystones of which are inscriptions, which may be taken as suggesting that the chapel was erected prior to 1411 by THOMAS CHILLENDE, the Prior.

SYDNEY HOUSE OF REPRESENTATIVES.

AN illustration is given of the principal front of the proposed Parliament House in Sydney, and another of the interior of the Chamber, as designed by the Government architect, Mr. W. L. VERNON.

THE CHOIR STALLS, CANTERBURY CATHEDRAL.

ALL the visitors to Canterbury Cathedral during the late celebration could hardly have been aware that the choir stalls are not more than twenty years old. On May 5, 1876, a meeting was held in the library of Lambeth Palace for the purpose of considering a project for refitting the choir of Canterbury Cathedral and restoring the stalls to the state in which they were placed by HENRI D'ESTRIA in 1305. The cathedral was for a long period in charge of the AUSTIN family as architects, but for so important a work as the transformation of the choir the aid of Sir GILBERT SCOTT was invoked. The following report on the subject was prepared by him :—

As a preliminary to the consideration of the treatment most suitable to be adopted in the restitution of this magnificent choir to a condition consistent at once with its architectural dignity, its present uses and requirements, and with ecclesiastical propriety, it would seem desirable, as far as possible, to ascertain what was its former state; and, as that has been necessarily subject to changes during the three and a half centuries intervening between its reconstruction by William of Sens and his successor about 1180, and the suppression of the monastery with the foundation of the college of secular canons in 1541, it may be well to aim at ascertaining, as far as may be, its state at about the last-named period, which may be said to close the Mediæval history of the cathedral.

We have little information as to the internal arrangements and fittings of the choir at the period of its reconstruction in the twelfth century; indeed, from the haste with which it was re-entered by the monks in 1180, it would seem impossible that its furniture could not have been other than temporary; and it is not improbable that the fittings generally were, at a much later time, considered hardly worthy of the structure, and that they were in great measure replaced by Prior Henry d'Estria early in the fourteenth century.

The only feature in the choir (beyond its mere structure) which appears to be of earlier age is the lower part of the walls which back the stalls; these are, from their character, clearly of the time of the two Williams; and are, indeed, distinctly recorded by Gervase to have been erected in 1180 by the English master.

The Patriarchal Chair may also be said, notwithstanding its repeated wanderings, to belong to the portion of the church under consideration. It is of early date, though its precise age is difficult to determine. It seems, however, reasonable to attribute it to the period of reconstruction, from its being of Purbeck marble, which does not appear to have been used in the church before this time, and from the improbability of the more ancient throne escaping the conflagration.

The high altar then occupied a position quite distinct from that in which its successor is now placed, having been, according to Professor Willis, nearly two bays to the westward, and less than half-way up the great flights of steps leading towards the Trinity Chapel. The Patriarchal Chair stood, as it is suggested that it ought still to be, at the head of those steps; whence it was moved, probably in Charles II.'s time, into Becket's Crown, and more recently into the south-eastern transept.

Beyond those above mentioned, it is probable that no feature of the choir, as seen at the period of the foundation of the collegiate body (excepting only its glorious structure itself), dated earlier than the time of Prior Henry d'Estria.

The most obvious of the remaining works of that period are the beautiful screens which divide the choir from its aisles, standing as they do on the base of the English William's walls. This prior is recorded to have "decorated the choir of the church with most beautiful stonework delicately carved;" and, in another document, his works are described as "The reparation of the whole choir, with three new doors, a new screen or rood-loft, and the reparation of the chapter-house," &c.; and, as the latter document is dated 1304-5, we know what was about the date of the work.

These side screens remain entire, except where interfered with by subsequent monuments. Those which formed the backs to the stall-work are placed about in a line with the inner face of the pillars; but those towards the east, at about the line of their centres. They are close walls to about a yard above the level for the elbows of the stalls, and above that line develop into beautiful pierced screen-work, crowned by a rich and exquisitely designed cornice, frieze and battlement; while portions which are entangled among the later monuments retain fragments of a beautiful decorative colour and gold, indicative of the original treatment of the entire screen-work.

Now this bears witness to a mode of treatment almost unique among English cathedrals; that is to say, that the stalls were without canopies, and backed by pierced screen-work. There is a sort of parallelism with this in what has been discovered to have been the arrangement at Rochester, where

also there were no canopies; but as in that case there are no pillars and arches, but closed walls, the stalls were backed by the wall itself, which was richly decorated in colour and gold. At Exeter also the screens which back the stalls are crowned by a cornice and parapet very similar to those of d'Estria; but as the screens themselves had been replaced in the sixteenth century by brick walls, we do not know what was their design.

These screens at Canterbury were, early in the last century, concealed from the choir by the introduction of wainscoting, which, however, has been for some forty years removed.

Towards the west, the choir is still concealed by canopy-work, erected in the time of Charles II. This canopy-work is of beautiful design and execution, but behind it remains d'Estria's rood-screen, which, though particularly seen on some previous occasions, especially by the late Mr. Austin, has been now again brought to light, and more minutely examined than before, and careful drawings have been made from it. It consists in the main of a continuation (with some variations) of the same beautiful design with the side screens, subject also to this difference, that the whole of the coloured decoration remains. This, however, does not apply to the entire width, being intercepted in the centre, not only by the doorway, but by the first or official stalls on either side, which, unlike all the others, have had overhanging canopies of stone, now cut away, as is also the case with most of the details of the doorway.

The screen-work, as it exists at this western end, does not actually meet that of the sides, being severed from the Norman piers, which project in the internal angles. The painted decoration was, however, continuous, the intervening spaces being occupied by a painted representation of the screen-work (or rather of its colouring), which is also continued over the stone canopies which flank the entrance.

The space between the level of the elbows of the stalls and the sills of the pierced screen-work is boarded (probably for greater comfort), and is painted and spangled with gold rosettes, with a rich border on the upper edge which continues across the Norman piers.

There can be no doubt that these remains of original decoration are indicative of that of the entire screen-work of d'Estria's choir.

Returning, for a moment, to the eastern screen, it may be mentioned that the design of the central doorway is left somewhat doubtful through the mutilation it has suffered; but there are proofs of there having been a figure, or a group of figures above it, the canopy over which was renewed, on an altered design, when the western side of the screen was reconstructed, a century later; the precise designs of the two canopies of the official stalls are also open to conjecture, though d'Estria's splendid canopy in the chapter-house may offer some suggestions.

Whether the stalls themselves were of d'Estria's time has not yet been absolutely proved; but the expression "Reparation of the whole choir," united with the fact of the screen which backs the choir being of that age, seem to render it probable.

A portion of the horizontal elbows of the stalls has been found to exist among the timbers of the floor of the seats, and this, so far as it can be examined, is not inconsistent with d'Estria's date, while the width, from centre to centre, of the stalls, as shown by that fragment, agrees accurately with that of the compartments of the side screens. Possibly more of the work of the old stalls may be found beneath the floor, as they existed till 1704, when the present seats were substituted, and it is not unlikely that they were in part used as materials for the new floors.

Assuming, then, that the renewed stalls should agree in character with the screens by which they are backed, they should be designed in conformity with such ancient stalls as we possess of about the same period, among which may be mentioned those at Wells and Ely. The desk-ends and fronts, with the stalls or seats in front, must also be designed in conformity with those of the same period, which in this country happen to be extremely rare. The old stalls are described by Somner as being in "two rows on each side, an upper and a lower;" but whether both were actually divided into stalls is uncertain, though probable.

The double rows of stalls would be extremely handsome, and add much to the dignity of the effect; but would accommodate a smaller number of persons than undivided seats.

In the above remarks, the stall-work is supposed to be wholly renewed as nearly as may be imagined to its old design; the two stone canopies and the central doorway between them, with the niche-work over it, restored; and the screen-work, so long concealed, at the west end, exposed to view, its beautiful decorations being carefully made good where injured. One may here add that, as this would displace the canopies of Charles II.'s time, some worthy place should be found for them elsewhere.

The decoration should then be continued along the side screens, the space between the stall-backs and the sills of open work being filled in with boarding and decorated like that dis-

covered at the west end. This boarding was probably, as before suggested, introduced for the sake of greater comfort. It might be desirable to have tapestry hangings for this space, if only for occasional use. We find that there were formerly hangings against all these screens, "for extraordinary occasions." These were provided by Prior Godstone in the fifteenth century. The hooks for these (which remain on the western screen and at intervals throughout) show that they hung from the cornice, and consequently concealed the open screen-work; and we learn that those on one side were wrought with "The history of our Saviour's actions," and those on the other side with "The life and death of the Blessed Virgin."

In arranging the stalls a space must, of course, be left as at present for the organist.

It is impossible to form four ranges of fixed seats with fronts, as at present, on either side; but one regular seat in addition to the two ranges of stalls may be formed, and movable seats may be placed in advance of them.

The rest of the accommodation should be obtained, as far as possible, by means of chairs; and it will be worth consideration whether, by removing the plate-glass which now fills up the open screen-work, the aisles of the choir, and even partially the eastern transept, may not be made available as a place for the overflow of the congregation. Persons so placed could probably hear even though they might see but little; and this might be facilitated by an altered position of the pulpit. The uses of plate-glass have been in a great degree obviated by the warming of the cathedral.

The next consideration is the position of the altar table.

Its removal, as at present, from its ancient place to the very top of the flights of steps, seems a very marked exaggeration of the idea of a "high altar." Its height is, indeed, so excessive as to sever it almost wholly from the region of the choir and the congregation; while the beautiful ancient arrangement—a relic of those of the Basilica of Augustine—by which the Patriarchal Chair was placed at the extreme east, was, by this position of the altar, rendered impracticable.

It is worthy of consideration whether an approach, at least, to this most interesting ancient arrangement may not be recovered; placing the venerable Patriarchal Chair behind the altar table, as in primitive churches, and among them in this, which from the time of Gregory the Great has been the Metropolitan and Patriarchal Cathedral of England.

The other arrangements of the interior need but little remark. The brass lectern would retain the position marked out for it in the old pavement; the litany desk would be placed in a suitable position; a reredos seems not to be wanted, as it would be an obstruction between the archbishop's chair and the altar table; an open screen, perhaps of metal, would occupy the position of the present reredos. Some description of sedilia, probably of wood, would be necessary, as well as such other minor accessories as might be thought needful.

There was much opposition to the proposal on the part of the Society for the Protection of Ancient Buildings. It was stated that the woodwork was remarkable for its intrinsic beauty, and was a noble example of the art of its period, while it in no way interfered with the architectural effect of the building. As the remains of Prior D'ESTRIA'S fittings were in a very fragmentary condition, the restoration of them must be conjectural as to design and modern as to workmanship. The Society was convinced that, however lamentable former destruction of ancient fittings may have been, the restoration of them was impossible and could only lead to a condition of things still more grievous to all lovers of art, and still more destructive of the history and dignity of the cathedral.

The cathedral authorities and their friends, however, gained the upper hand. The proposals of Sir GILBERT SCOTT were realised, and we imagine that few people who are competent to judge will be found to regret the removal of the eighteenth-century woodwork.

ROYAL ARCHITECTURAL MUSEUM.

THE annual meeting of the Royal Architectural Museum and Westminster School of Art was held at the Museum, Tufton Street, Dean's Yard, on Friday afternoon, the Duke of Westminster (president of the Society) in the chair. On the motion of Dr. Garnett, seconded by Mr. Sidney Lee, the Duke of Westminster was reappointed president and the vice-presidents were re-elected.

Mr. Maurice B. Adams proposed the adoption of the report, which stated that the council had acquired the premises adjacent to the museum for the purpose of building additional classrooms. The new building was now in course of erection at an estimated cost of 2,630*l.*, exclusive of architect's charges,

and was to be completed by Christmas next. The total income for 1896 amounted to 1,912*l.*, of which the School of Art in fees and grants contributed 1,821*l.* The expenditure reached 1,330*l.* The adoption of the report was seconded by Mr. W. Pain and carried.

In replying to a vote of thanks, the Chairman said that there could be no doubt of the immense advantage which it would be to the school to have the additional premises now being added to the Institution. He called attention to the fact that a substantial amount of the funds necessary to carry out these alterations remained to be found and that, as on most occasions of this sort, they had to appeal to a generous public to supplement with their contributions the efforts of the Society.

The Secretary announced that he had just received the results of the examinations held in May last in connection with South Kensington. Out of fifty-three candidates entered for drawing from the antique thirty-six succeeded; in drawing from life sixty-one candidates were sent up, of whom fifty-nine succeeded, eight obtaining "excellent"—the highest award; and in anatomy eighteen candidates entered, of whom thirteen succeeded.

THE STATE AND TECHNICAL EDUCATION.*

WHILE as early as 1833 the State had begun to foster primary or elementary education and to assist it with grants from the public funds, it was not until many years later that the claims of secondary or intermediate education entered the sphere of practical politics. It is true that, owing to the appointment of the select committee of the House of Commons in 1835, the art education of this country was aided from 1836 onwards by annual Parliamentary grants, which, beginning in the latter year with a sum of 1,500*l.*, amounts at the present time to a total of little short of 320,000*l.* per annum, by far the largest part of which, however, is allotted to the teaching of drawing in elementary schools. General science teaching was first rewarded by Government grants in 1859, and the sum set apart for the science education of the country for the present year amounts to nearly 200,000*l.*, disregarding for the time being the large sums received for this purpose under the local Taxation and Excise Act of 1890.

In the admirable "Historical Sketch" prefixed to the recent report of the Royal Commission on Secondary Education, it is stated that it was not until 1861, when the Royal Commission was appointed to inquire into the condition of nine among the chief endowed schools of the country, that what is now called secondary or intermediate education began to engage serious attention. This Commission, presided over by Lord Clarendon, reported in 1864, while a second Commission appointed in December of that same year, the so-called Schools Inquiry Commission, presented its report three years later, in December 1867. The outcome of the first of these Commissions was the Public Schools Act of 1868, while the issue of the second Commission was the Endowed Schools Act of 1869. Among other provisions of this latter Act was the appointment of a permanent body termed the Endowed Schools Commission, entrusted with large powers for the better government and management of schools of this character. In 1874 this body was by a subsequent Act of Parliament merged in the Board of Charity Commissioners for England and Wales. Under these public bodies schemes for upwards of 900 schools have been framed and approved out of a total of 1,448 endowments in this country known to be subject to the Acts, but a considerable number of endowments founded less than fifty years before the passing of the Act of 1869 have until now been exempt from its provisions.

The Elementary Education Act of 1870 had undoubtedly the most far-reaching effects in establishing the primary education of the country upon a sound and systematic basis, and when it becomes necessary to study the question of more advanced instruction, the recent tendency of certain of the public bodies, created under that Act, to provide education for children beyond the limits for which the primary schools were originally designed, must receive careful attention. Schools of the type known as "higher grade," "higher standard," or "seventh standard schools," have been established in certain of the large towns with the avowed intention of taking up the work of education to a point beyond that at which the elementary school leaves off. As is well said in the report of the Secondary Education Commission, "these schools, though they have received the name of 'higher grade elementary,' are really secondary in their character, so far at least as regards their higher classes, in which instruction beyond the standards is given." As these schools can only share to a very limited extent in the grant distributed by the Education Department, they are supported partly by the fees of scholars, but mainly by the grants of the Science and Art Department.

This brings me to the consideration of the principal Govern-

* A paper by Mr. Gilbert R. Redgrave, read before the International Congress on Technical Education.

ment agency for the promotion of secondary and technical education in this country, namely, the operations of the Science and Art Department, and in this connection I desire to speak more particularly of the work of the Organised Science Schools called into existence under that Department. The State first took a part in diffusing a knowledge of the arts and principles of design among the people (especially the manufacturing population) of the country by the establishment in London in June 1837 of the Normal School of Design. In 1840 the Government decided to extend their assistance to the manufacturing districts, and authorised a grant of 10,000*l.* towards the formation and equipment of schools of design in certain of the larger provincial towns. Ten years later, in 1850, when considerable changes had been from time to time introduced into the management of the school in London, there were sixteen provincial schools of design in Great Britain and Ireland, with about 3,000 pupils under instruction, and in 1852 a so-called Department of Practical Art was called into existence under the Board of Trade to administer these schools and to promote and foster the general art education of this country. A year later the new Department was much enlarged in its scope, and became from thenceforth known as the Department of Science and Art.

This state of things continued until February, 1857, when the Education Department was constituted to include (a) the Education Department of the Privy Council Office and (b) the Department of Science and Art, and these two departments were placed under the Lord President of the Council, assisted by a Vice-President of the Committee of Council on Education. It will thus be seen that the Department, originally organised to deal with the art work of the country, was subsequently entrusted with administrative machinery by which grants are distributed in aid both of science and art. Its annual grants began, as we have seen, to be made as far back as 1837, and though these grants were not originally made to schools except such as those in which art alone, or later those in which science in conjunction with art was taught, yet, as pointed out in the report of the Secondary Education Commission, the tendency of more recent "legislative and general changes in education has been to render them grants to scholars in schools."

The work of the Science and Art Department and the syllabuses of its examinations originated with the requirements of the art school, the art class, or the evening science class, and the examinations have from time to time been modified to make them more generally applicable to the needs of scholars in schools, rather than to those preparing for an art designer's career, or to those attending the night classes at mechanics' institutions and schools of a similar type for whom they were, as already stated, in the first instance chiefly intended. It is, indeed, largely owing to the new type of students taking advantage of its grants in the higher grade schools in provincial towns, to which reference has already been made, as also in endowed schools or grammar schools, that certain recent developments in the work of the Department, culminating in the establishment of the so-called organised science schools, have been introduced, and it is to this aspect of its operations as bearing on a State system of secondary education that I desire to chiefly dwell upon the present occasion.

At the very inception of the scheme of State grants in aid of science teaching in 1861, there were ready to hand, besides the isolated classes in architectural and engineering drawing, physics and chemistry in some of the chief mechanics' institutes, a certain number of schools scattered through the country in the nature of engineering schools, navigation schools, or trade schools in which a considerable amount of time was devoted to science teaching, some of these schools being due to the early action of the Department, from 1853 onwards, and these were prompt to avail themselves of the examinations and grants offered to them by the Science and Art Department. In the course of time, as teachers became trained, classes in the various subjects of science were multiplied, being very largely in the nature of evening classes, and one of the reproaches levelled against the work in connection with South Kensington was the sporadic character of many of these classes and the want of continuity and completeness in the course of study pursued by those who were trained in them.

The chief attempt to remove these objections was the institution of the Organised Science Schools, or secondary schools, in which a definite course of science work was enjoined, and in which the curriculum laid down was such as to insure a due sequence in the subjects studied and in the correlation of one branch of work with another.

The name adopted for the schools of this type, though it is sufficiently explanatory of its object, is not free from objection, being no doubt cumbersome and in some of its applications misleading, but as the appellation in question is about to disappear we need not now discuss it further.

Various advantages in simplified registration and in capita- tion grants were held out to induce school authorities to avail themselves of these special schemes, and the organised science schools under the Department have steadily increased both in

number and in importance. Very early in their history it became manifest that these schools would embrace institutions which were originally of widely differing types, for while, on the one hand, the scheme was adopted by many of the higher grade schools, to which attention has already been drawn, frequented almost entirely by ex-standard scholars of the public elementary school, the course was shown to be readily applicable to the modern side of the grammar school, and, with slight modifications, to the day technical school of still more recent growth. The tendency in the grammar school was to press for a reduction of the time devoted to the science and art teaching, and in the technical school the literary teaching was in some cases brought down to the vanishing point. It soon became evident that schools of this character, conducted upon the lines laid down by the Department, were admirably adapted for the education needed by the middle classes of our large manufacturing towns, and that by the introduction into the prescribed courses of certain modifications, such schools might become the State secondary schools of the future, carrying on to its necessary conclusion the excellent education afforded by the best Board schools, and serving to provide such a ground-work in science as would furnish the soundest possible preparation for the technical high school or science university. My intention is now to indicate how these various aims are provided for in the amended curriculum of the State science school.

The Secondary School Commissioners in their recent report have well defined secondary education, which is inclusive of technical education, as "education conducted in view of the special life that has to be lived, with the express purpose of forming a person fit to live it." A good type of a school providing this education is stated to be "less literary than the grammar school, less theoretical than the science school, and distinguished from both by its functions being mainly industrial." The modern science school, as I understand it, draws its population from the lower middle classes, almost entirely from the children of parents who cannot afford to keep them at school beyond the age of eighteen. In the case of a very small number of its students provided with bursaries and scholarships, or the children of more well-to-do parents, it may be possible to proceed to the technical college, but the large majority of the students will end their education here and will quit the school to earn their own living. This fact must limit the course in most cases to three years, but it becomes possible, by the provision of a fourth year's course, to meet the requirements of those who will matriculate for the university or who will complete their education at the technical college.

The work of the so-called elementary course of the science school is designed to extend over two years, during which a thorough progressive course of education in science, combined with literary and commercial instruction, must be given. It is an important feature in this part of the scheme that students whom the inspector reports to be unfitted for the work will be excluded. The elementary course, as laid down in the directory of the Science and Art Department, comprises five obligatory subjects of instruction, namely, mathematics, elementary physics, including the fundamental principles of mechanics (theoretical and practical), elementary chemistry (theoretical and practical), freehand drawing and elementary practical geometry. It is stipulated that, while the course may extend over two years, all the subjects must be taught in each year, the instruction in the second year being more advanced than that of the first year. It is intended that the teaching should be such as to form the basis of future studies in science, and the students, during this part of their education, are not submitted to examination, but their work is tested by the inspectors of the Department in the course of frequent visits. Not less than thirteen hours per week must be allotted to the instruction in the above obligatory subjects of science and art, eight hours of which must be devoted to the teaching of subjects other than mathematics, and not less than ten hours per week must be set apart for the literary subjects, which may include two hours given up to manual instruction, or, in the case of women students, to cookery and needlework. It will thus be seen that twenty-three hours per week must be devoted to subjects of the time-table, over which the Department exercises direct control, and further regulations apply to the length of the lessons, the number of students under each teacher, the marking of the registers, and to other matters of detail which need not here be specified.

On the completion of the elementary course, the intention is that the work of the students should be specialised in one or other of a series of advanced courses, several specimens of which have been drawn up suitable to the needs of students who may desire to devote their attention either to physics, mechanics or biology. It is pointed out that other special advanced courses, such as for mining and agriculture, may be sanctioned, but it is necessary that they should be previously submitted to the Department for approval. In all these courses a considerable amount of latitude is allowed to the teacher, provided the instruction is sound, satisfactory in

amount and combined with proper practical work. In the case of the advanced courses, certain obligatory and optional subjects are laid down, and, as in the elementary stage, sanction is given to extend the work over two years, but the second year's curriculum must be submitted to the Department for approval. During this second year the time devoted to literary subjects and manual instruction may be curtailed to six hours per week.

The education of women students is specially considered, and in their case instruction in certain subjects of biology may be substituted for physics in the elementary course, and where this is done a special advanced course has been drawn up for their use. In many of the existing schools both sexes are being taught together with excellent results.

A liberal scale of payments has been devised for these schools, based partly upon capitation grants upon individual attendance, partly in the form of a variable grant dependent upon the result of inspection, and partly as a grant for practical work done in suitable laboratories. In the case of students in the advanced course, payments are made upon the results of examinations conducted by the Department in the ordinary subjects of science and art, and payments may also be claimed on account of manual instruction or for the needlework and cookery of the women students.

It has been found that in a well-equipped science school, properly staffed, and attended by students of suitable age, who have been carefully trained in accordance with the prescribed syllabus, that grants averaging from 4*l.* to 6*l.* per head can readily be earned, and it is estimated that schools coming under the scheme can in certain cases obtain in grants more than three-fourths of the total expenditure per scholar. Of course it is not intended that the State should pay the entire cost of this education, but it has been publicly stated that in certain of the higher grade schools the grants from the Science and Art Department are sufficient to cover all expenses except the rent.

From this brief outline of the regulations for these schools it will, I think, be evident that we have here all the conditions needful for the suitable training of the large majority of the young people of both sexes in the country, who would in the natural course of events enter the secondary school. In the case of a relatively small proportion of the children of the upper middle classes, who may look forward to entering the university, there is the classical training of the grammar school and the public school, existing upon lines which have been pursued from time immemorial, and concerning which I have no desire to speak at the present time, but the curriculum of the grammar school is ill-fitted for modern requirements and for the training of the vast majority of the children of the middle classes who have to look forward to an industrial or a commercial career. Something of the nature of the German Real-Schule, but with a far larger proportion of practical science work and manual training should, I am convinced, serve in the future as our model for the secondary school in this country, and I believe that it is quite possible to expand the scheme of the State science school, such as I have described it, so as to embrace all those branches of a modern education, whether literary, scientific or commercial, which can possibly be required by young people between the ages of fourteen and eighteen. I look forward to the time when each large manufacturing town and every county town of importance will possess its State-aided and State-inspected modern school, and I am convinced that in the organised school which I have attempted to describe we have all the necessary elements of the institution in question. Each of these schools will, of course, be adapted in its details to the special needs of the locality in which it is situated.

I have purposely avoided all mention of the details in the work needed for different types of schools, but it would be easy to show that in the case, for instance, of a commercial or an agricultural school certain readily introduced modifications in the curriculum would convert this or that section of the school in the one case into an agricultural division, in the other into a commercial school. For schools of the latter type we have excellent models in Antwerp, Vienna and certain other continental cities, where the youth is trained to be a clerk almost as if he were in the counting house of a merchant's office. He sends and obtains samples, analyses them in the school laboratory, tests their relative values, fixes the prices, sends invoices and corresponds with imaginary agents, manufacturers and travellers in several languages, and he sees in the school museum fine collections of commercial produce from every part of the world. We have really no example in this country of a commercial school established on modern lines. Agricultural schools already exist in England and will furnish useful types of the class of changes which will have to be introduced in the syllabus in order to render the State-aided school suitable for a specialised training in agriculture.

There are many other directions in which the school or sections of the school may have to be modified, since it is quite

evident that no narrow or rigid curriculum would suit every case, and to my mind the great value of the syllabus consists in the obligatory nature of a fixed amount, both of literary and scientific instruction, with the power to take up other voluntary subjects capable of giving a special direction to the work of the school.

I wish it to be clearly understood that I have purposely here omitted all reference to the other directions in which the State intervenes in order to aid the science and art work of the country, namely, in the system of evening classes and in the fully equipped school of art or in the simple art class. The art work may be disregarded, as it forms but one small branch of technical education. The science work, however, stands in a wholly different position, and the training in practical science and in manual work, which has been largely stimulated by State grants, must, I think, be regarded as among the most important and valuable of the results of State intervention in secondary technical education.

THE GREEK ROSE.

THE rose, as described in the Anacreontic odes and as familiarly known in modern times, is acknowledged to be the product of cultivation; the original plant, from which all our varieties have proceeded, being the common wild-briar. Such is the rose which Theophrastus describes in his "History of Plants" as alone commonly known in Greece, and although the process by which the simple blossom of the wild-briar is converted into the fine double rose does not appear to have been altogether unknown to that naturalist, yet the language he uses in speaking of the artificial production implies that he had never had an opportunity of seeing it. This testimony is confirmed by the accounts which have come down to us of the state of horticulture among the Greeks, that people having been wholly unacquainted with gardens in the modern sense of the term before the time of Epicurus. Further evidence to the same purpose is derived from the fact that the garlands used by the Greeks upon festive occasions were composed of such ordinary plants and herbs as myrtle, coriander, feverfew (*Pyrethrum Parthenium*), parsley, &c.; the custom of interweaving them with flowers was not introduced before the 100th olympiad. Such likewise was the composition of the crowns celebrated by the early lyrists, including the genuine remains of Anacreon preserved by Athenæus. The period when Theophrastus published his work, in which he gives the above account of the rose as known to the Greeks, at which period the horticultural art was in a state quite incapable of producing flowers corresponding in beauty and fragrance with those celebrated in the odes, was the 116th olympiad; while the period when Anacreon flourished cannot be brought lower than the sixty-fifth, being a difference of more than two centuries. While, however, the cultivated rose appears not to have existed in Greece in the age of Anacreon, the term *rodon* afterwards applied to this flower was in use not only at that period, but even in the times of Homer. The word *rodon* is of oriental derivation; its elements are employed by the Hebrew writers and by Homer to express not specifically the rose, but generally any flower used in dyeing; in this sense it was applied to the lily, the plant madder, the privet, &c. On assuming that the rose was the first flower to which it was applied, and the type from which all others so termed derived their appellation, it is inconceivable that these plants should have been at all termed roses, and inexplicable that they should have been called, as was the case, the dog rose, the red rose and the white rose; but on the supposition that the term signified a dye-flower, no name so appropriate could be applied to them as the dog dye-flower, the red dye-flower and the white dye-flower, they having all been employed in the art of dyeing. The flower which assumed to itself the name of the dye-flower *rodon* was the blossom of the pomegranate, or balaustium. The dye extracted from this flower was red, and hence the word appears to have been applied to all flowers of a red colour. We learn from the scholiast on Pindar that it was from its being celebrated for its dyes, which were obtained from the pomegranate, that the island of Rhodes received its name. Should, however, any reasonable doubt be entertained respecting the signification ascribed to the term under consideration, it is certain that the plant, whatever it was, to which it was assigned, obtained but a moderate share of admiration—if we except the suspected odes, in which a flower so-called corresponding to our modern rose is celebrated with an excessive and unexampled partiality. The balaustium having been superseded in its application to the art of dyeing by the brighter colour drawn from the murex, gradually sank into oblivion; while the rose, obtaining increased attention, fixed the general admiration and finally appropriated the name which it at first received by adoption. Shortly after the publication of Theophrastus's "History of Plants," at which time it was comparatively little known, its cultivation was extensively spread and the partiality for it fully established. From Greece the "garden queen" found its way into the Italian soil, and through

France was spread over all the west; while its reception into every European garden was accompanied by the adoption of its name into all the European languages.

LOUTH AND ITS ARCHÆOLOGY.

THE members of the Architectural and Archæological Society of the counties of Lincoln and Nottingham made a visit to Louth on the 6th inst. The attendance was large. Leaving Louth shortly after 10 o'clock the party proceeded on an excursion in the marshes, in which there are numerous objects of particular interest to an archæologist. On the outward journey Grimoldby, South Cockerington, South Somercotes, Skidbrook and Saltfleet were visited, and the churches of these places, with their many objects of interest, were inspected and much admired. At Saltfleet the party were particularly interested in the history of the old-time seaport town, which was partly destroyed, together with the church, by the incursions of the sea, and which in 1359 furnished two ships of war and 49 men to the navy of Edward III. for the invasion of Brittany. Having had lunch, the party commenced their return journey, halting at Saltfleetby St. Clement's and All Saints Theddlethorpe, All Saints, Great Carlton, and Legbourne. At Legbourne the party's attention was drawn to the priory of Cistercian nuns, founded by Gilbert de Lekeburn before the reign of King John. The church of All Saints was also inspected. It is chiefly built of chalk. The dinner at night was followed by a public meeting, at which the mayor of Louth (Ald. H. D. Simpson) presented an address on behalf of the Corporation and burgesses. The address expressed a cordial welcome to the Society; referred to its foundation at Louth in 1844; to the occasion of the Society's last visit some twenty-two years ago, and to the loss the town and the Society had sustained by the death of Ald. Fowler. The address also assured the visitors that the inhabitants of Louth recognised the advantage of the periodical visits of the Society to the churches in the diocese, and they trusted that their efforts would prove conducive to the preservation in their original beauty of the many sacred edifices which the piety of our forefathers had erected in nearly every parish in the diocese. An interesting paper, entitled "A Description of the Fabric of the Louth Church, with a Glance at its History," was given by Mr. J. J. Gresswell, A.R.I.B.A., and Mr. R. W. Goulding gave a capital paper, entitled "The Lords of the Manor of Burwell." An exhibition on a small scale was given in illustration of the papers.

THE PRESERVATION OF HISTORICAL PLACES.

AT the annual meeting of the National Trust for Places of Historic Interest or Natural Beauty, held in Burlington House on the 9th inst., the Duke of Westminster presided.

In moving the adoption of the report and statement of accounts the Chairman said they were now celebrating the third year of their Society's existence, and though it could not be expected they could do much at once, yet their progress could be reported as satisfactory. They had been able to secure Barras Head—that very noble headland near Tintagel—and they had also been able to report the completion of the offer of Mrs. Talbot to purchase from Lord Harlech and present to the Trust a further portion of Barmouth Cliff. Other interesting places had either been secured or were about to be secured, and they hoped to do more work in that direction as time went on.

The Secretary (Mr. A. M. Poynter) read a letter from Sir W. B. Richmond, R.A., who, in wishing the Society every success, urged them to go on in the manner they had commenced. He did not think the Legislature would take up such a matter at present. Private enterprise with a whole heart did so much in England. The thing was to get public opinion excited and to reach the Legislature that way. While he confessed to wishing the Government was ideal and highly æsthetic, as well as practical, he held that as matters were at present faddists were more likely to stir public opinion than any body of legislators. When they found the public on their side, by becoming at times pleasant and disagreeable, then would be the time to try the Government.

Mr. Fred. Harrison also wrote deprecating the arrangement which allowed private families to reside in the Tower, and hoping that active steps would be taken to prevent the building and its walls from being in any way desecrated.

Professor Geddes proposed, Sir H. Howorth seconded, and it was unanimously resolved, "That it is desirable that further facilities be given by legislation to private owners to place historic monuments and places of striking natural beauty beyond reach of destruction or injury."

THE PANTHEON OF POMPEII.

THE College of the Augustales, which is called on the spot the Pantheon, for no other reason than that twelve pedestals were found in its centre, is one of which the use is the least evident of any at Pompeii. The plan is, as nearly as possible, similar to that of the building misnamed the Temple of Serapis at Pozzuoli, but which is proved to contain the baths or thermæ of Puteoli, with their appropriate medicinal spring, now cleared and applied to its original use. In each of these edifices we find an open court, with its colonnades and little chambers, and in each we have a circular or polygonal tholos in the centre, corresponding with that which Pausanias describes at Epidaurus as the place where patients waited till they could enter the bath. In each we find, exactly in the same relative situation, a temple or building evidently more sacred than the porticoes; but these coincidences only serve to prove that the convenience of such a disposition of the apartments of public buildings was the motive for its frequent adoption in places serving for the union of any great concourse of people. Signor Carlo Bonucci, in his work printed at Naples in the year 1826, has called a part of the Pompeian edifice the Temple of Augustus, and considers the remainder as the scene of the sacred banquet of the Augustales; and there seems no reason to doubt this theory, except the difficulty of finding so large a piece of ground, in the centre of a city already built, for the erection of such a fabric, and for such a purpose, at so late a period. Yet Vitruvius, cited by Signor Bonucci, gives such a situation for the Temple of Augustus. The Augustales were highly honoured, as we are informed by Vegetius, being chosen by Augustus, the founder of the order, to lead the troops in battle, and they seem to have presided at the feasts and games called Augustalia, in honour of that deified emperor. Tacitus has given some accounts of the institution, and Lipsius has added almost everything else that was known of the Augustales, till the numerous inscriptions at Pompeii proved that they were of great consequence in that city, though neither their office nor their antiquity is likely to conciliate the respect of the moderns or give any interest to their history. They seem by one inscription to have been six in number at Pompeii. It appears, however, that the Augustales were possessed of funds which supplied them with the means of feasting and inviting their fellow-citizens to partake in the banquet, for which purpose the building now called the Pantheon was so well calculated that, whether belonging to a particular order or the common property of all the inhabitants of Pompeii, it may be safely considered as a place of feasting or carousal under the protection of some deity, who from his more elevated sacellum was supposed to overlook and patronise the banquet. That such was the destination of this edifice, and that it differed but little in its uses from that which the Greeks called Lesche, and the modern Italians a trattoria and coffee-house, seems to be rendered more probable by many of its internal decorations, while its proximity to the Forum, the chief resort of the inhabitants of the city, would point out this situation as the most eligible for a place of conversation and refreshment. Pausanias, in his account of Delphi, describes a building called Lesche, which, he says, was a place of meeting and conversation common in many of the more ancient cities of Greece, where, says Harpocration, citing Cleanthes, the Lesche was sacred to Apollo. In that was a temple, as in this at Pompeii, and the walls were covered with paintings, some of which represented the very personages repeated on the walls of the Pantheon of Pompeii. The Lesche of Lacedæmon was even called Poikilos, or painted, and as most of the smaller temples had little light these pictures must, like those of Pompeii, have been disposed on the walls of the portico or peribolus. The Lesche of Delphi, among other historical paintings had many Homeric subjects. Ulysses, Ariadne, Theseus, Penelope, Phædra, Bacchus and Æthra were among the personages represented there, and we find many of these on the walls of the Pompeian edifice, with other scenes taken from Italian history. It must be confessed that this coincidence of ornament proves little more than that the plans and decorations of many public buildings were not very dissimilar; as a portico surrounding a court with a more sacred portion at one extremity would be the characteristic of the greater number of them. That feasting, however, was the principal motive for assembling in the porticoes of Pompeii may be presumed from the subjects of many of the smaller paintings. The street which runs along the north side of the Pantheon from the Temple of Jupiter has been called that of dried fruits, from the number of figs, raisins, chestnuts and plums, fruits in glass vases, lentils, hempseed and other objects of the same kind found in the shops. Bread, scales, money and moulds for pastry were among the discoveries; and a bronze statue of Fame, of small size and fine work, with golden armlets. We find at the northern entrance—which has on a pilaster the name CELSUM, and near which was found a box containing an engraved stone set in a gold ring, with 41 silver medals and 1,036 brass coins—cupids employed in making bread or driving the ass, crowned with a wreath, that brought the flour. On the opposite side they are employed in making garlands for the guests. On

the wall at the southern entrance is painted a hatchet for cutting the meat; while hams, boars' heads, fish and other viands compose the picture. In other places we find geese, turkeys, vases full of eggs, fowls and game ready plucked for roasting, oxen and sheep, dishes of fruit and a cornucopia poured out, with a variety of amphoræ for holding wine and every sort of accessory for the banquet. To the evidence of the pictures may be added that of a drain or sink near the tholos or dodecagon in the centre of the court, which was found obstructed with bones of fish, and other indications of the remains of articles of food.

TESSERÆ.

The Towers of Bologna.

BOLOGNA is one of the most remarkable cities in Italy, and one at which any student in history should make a halt to examine it. Nowhere else can we see arcades and colonnades of three miles long; and the celebrated leaning towers are quite unique. The fact of their leaning over so much out of the perpendicular without falling is a proof of the strength with which they are built and the excellent mortar that was used; they also serve to illustrate an interesting chapter of Mediæval architecture and customs. There was once a tower to every house of importance in Italy; it was one of the marks of rank, but they were also important means of defence. The artillery of those days consisted of paving stones, and whoever could throw them from the greatest height had the most powerful castle. The bottom, or ground-floor, of these towers is frequently solid to make a secure foundation and to resist the battering-ram. The entrance was frequently on the first floor, and the steps drawn up (as in Irish round towers), and each succeeding storey could be defended in the same manner. When they had attained sufficient height, an arrangement was made to throw out on all sides a wooden scaffold or balcony, called a *hourd*, on which the defenders could stand and from which they could throw down large stones on the heads of assailants, and on which they could also probably fix catapults to throw them to a distance. Holes through a wall on the level of the floor, to pass the poles through, remain, so that a *hourd* could be thrown out at any time even now. Such scaffolds, resting on poles placed horizontally and passing through the wall, with sloping brackets under them to strengthen them, are in common use in Rome by the builders at the present time; a scaffold is seldom brought down by vertical poles to the ground after the first floor is built. These leaning towers are a tremendous height, each succeeding generation having carried them a storey higher in constant rivalry one with the other; he whose tower was the highest had the command of the others. The two that lean in different directions are higher than the others and near together, but were separated by a street and belonged to two different families. There are remains of many others of these towers in Bologna, and they are common in all parts of Italy.

The Aristion Relief, Athens.

In the Theseum stands the celebrated monument of Aristion. It is certainly as old as the Persian wars, if not older. But who was Aristion? We have no information of any kind about him; he is represented in the usual armour of a hoplite; he was an ordinary Athenian citizen. How completely, then, must he have already penetrated all the pores of Attic life, when a monument, ranking among the most perfect works of art, was erected to this simple man, neither eminent in point of rank nor distinguished by any memorable deed. It is in very low relief; all the older works disdain the slightest approach to statuesque rounding. The pillar, of Pentelic marble, is high and narrow, and the form, in conformity with the confined space, of slender but firm and vigorous make. The worthy hoplite strides onwards with slow and measured steps, his head bent a little forward, his mouth drawn into that good-natured smile which invariably appears in all the more ancient works of art. In his left hand he holds the lance, one end of which rests on the ground; his right hangs close by his side. The simple worth and manliness of the old Marathonian speak from every feature. The anatomic forms and proportions are so rightly understood, the muscles so vigorously thrown into prominence, the transitions and outlines so sharply and yet so finely given, and the cuirass and greaves which protect breast and shinbone handled with such a masterly feeling of their character as thin, flexible metal, yielding to every impression of the body, that the effect of this work is only the more powerful, the more clearly we see from the long, lean figure, the forced smile, and the methodically combed and curled hair of head and beard, that we have here to do with a production of an early and imperfect period.

Optical Delusions.

To make a building appear much smaller than it really is may be a proof of skill in the architect; but the English architects aimed at the opposite effect—to make it appear as large

and especially as long as they could, and the large number of small narrow arches produces a wonderful effect of perspective, and gives apparently endless length to many of the English cathedrals. This appears to give them a much finer effect to the eye, and to produce a more religious impression on the mind than the opposite extreme. In some of the Italian churches, as in Sta Maria Novella in Florence, the arches of the east end towards the altar are smaller and narrower than the others, the effect of which is still more to shorten the church to the eye. Perhaps one object of this is to fix the attention more exclusively on the high altar with its fine screen.

Stained-Glass at Winchester.

The earliest specimens of English glass at Winchester are the two fragments probably of a border worked in with other glass in the west window of the nave of St. Cross, and two other fragments of a border over the door leading into the refectory. All this glass is of precisely the same character, and to be referred to the beginning of the thirteenth century. A few small fragments of later Early English are at present contained in the cloister of the college. Two circles of early decorated glass are over the door of the refectory of St. Cross, and two or three more in the west window of the cathedral. They are composed of plain pieces of coloured glass, disposed in a geometrical pattern, and prove how much of the effect of early glass is owing to the texture of the material. It appears to have been the practice formerly to glaze the windows according to the progress of the work. Thus at York the Decorated glass in the aisles is earlier than that in the west window of the nave, and the Perpendicular glass in the aisles of the choir is earlier than that in the great east window. All the glass in the side windows of the College Chapel, Winchester, is modern, as well as that in the east, with the trifling exception of two small figures, the head of an angel, and four other little bits of glass in the tracery of the window. Considering the time when the glass in the east window was executed, it must be admitted to be a very good copy of the old. The art of making coloured glass was not so well understood then as now. Had the glass been copied now, it would only have been one degree better than it is. Its effect would still have been that of painted glass, exhibiting the drawing of the early part of the fifteenth century and the colouring of the nineteenth instead of that of the sixteenth. The texture of all modern manufactured glass, uncoloured as well as coloured, is identical only with that of the sixteenth century, and is totally different from the texture of earlier glass. The principle of adapting the execution to the material pervades all ancient and indeed all original manufactured work, and it is vain to imitate the drawing without also imitating the material in which the work is to be executed. Hence it is that modern encaustic tiles, whatever may be the date of the pattern impressed upon them, always appear to be of the date of the manufacture of the tile. The east window of the College Library is of the time of Edward IV., and was moved to its present position from the south side of the college chapel. The arms in the refectory at St. Cross are of the latter part of the fifteenth century. Those of Cardinal Beaufort are uncommonly fine. The glass in the east window of the cathedral choir is perhaps a little earlier than 1525, and is the work of Bishop Fox, whose arms and motto, "*Est Deo gracia*," are introduced into it. This window must have been a magnificent one, but it is unfair to judge of it in its present state, when so little occupies its old position in the window. The top central light is filled with glass of Wykeham's time, and all the rest of the window with glass of Fox's time. In point of execution the painted glass in this window is about as perfect as glass could well be. The library at the deanery contains some excellent specimens of heraldic glass of the time of James I. and Charles I., in which, however, the decline of the art of glass-painting is very apparent.

Roman Buildings.

The roof, says Winckelmann, was either entirely flat or more commonly had a flat timber-work (*combe*) or terrace. In private houses all the cornice, upon which the roof in part bore, was made of terra-cotta, and in such a fashion that gutters might descend by it. Lions' heads for spouts was an Egyptian fashion, according to Plutarch, because the Nile overflows when the sign is Leo. Other accounts say that at Rome the conduits of the gutters in private houses were, in general, made with boards. Roofs of plates of silver, brass, &c., often occurred at Rome upon public or private buildings. Pliny mentions one which was fastened without nails, and could be taken to pieces at option. Pigeon holes in the roofs were common. The ceilings of Egyptian temples were either of slabs of stone, or sculptured, like the famous planisphere at Tentyra. The Greek temples at Athens had ceilings composed of marble slabs in compartments, and in the Temple of Minerva at Syracuse the long stones which connected the columns with the outer walls formed a ceiling in the style of a platband around the peristyle of the building. The ceilings of the most ancient temples were of wood, sometimes cedar or cypress, or vaulted. Those of

apartments were horizontal, of wood, and when they were formed only of planks, of which they covered the joists, they were named by the Greeks *phatnomata*; but when they had ornaments in square compartments (*renfoncés*), like those still in use in Italy, they were called *laquearia*. Those which had no ceilings or panels (*renfoncés*) were, in general, ornamented with works in stucco, as in a bath near Naples, with Venus Anadyomene, the Tritons, &c. The figures and panels were often gilt. Chambers which had no ceiling were vaulted with reeds bruised and flattened. The square temples, says Winckelmann, have, in general, no windows, and receive light only by the door, in order to give them a more august air by illuminating them with lamps. Some round temples have a circular aperture at top. In houses the windows were in general placed high, very small and square; tiers of them occur at Pliny's villa at Laurentum. The *valvate fenestra* were also windows from the ceiling to the floor. Glazed, and even bow windows have been found at Pompeii, but they were mostly closed with curtains, wooden shutters, or lattices hung upon hinges. It is not, however, true that the houses had no windows towards the street, though it was very unusual.

Salisbury.

The city of New Sarum, or Salisbury, unlike most other English towns, has its origin well defined and its prominent historic annals duly recorded. It has nothing Roman, Saxon or even Norman in its early annals, and is therefore distinguished from every other city of the kingdom. Of truly English origin, of unprecedented uniformity in plan and arrangement of parts, with a provision for cleanliness and healthfulness, Salisbury may be considered as peculiarly indigenous, unique and admirable. While every other city of England has or had its castle, and claims either a Roman or Saxon origin, we know that New Sarum was commenced under the auspices of a bishop, that it grew up under ecclesiastical, not baronial power and protection, and that though it was surrounded by fortified walls, it never had a monarchical or baronial fortress. The prefix "New" shows that there was an anterior Sarum, which obtained the name of "Old" when a younger and a new town was established. Old Sarum, about one mile north of the modern city, was probably at first a British town, and evidently a Roman station and fortress. At this city William the Conqueror "summoned all the estates of England and Normandy to swear allegiance to him, and to introduce one of the most remarkable changes that ever happened" in the English constitution—the establishment of the feudal system. In consequence of disputes, of "brawles and sadde blowes," as Holinshed states, between the clergy and the castillans, or men of war, the bishop and his associates removed their residences to a fertile valley at the junction of two rivers. There they built houses and commenced the present magnificent cathedral in the year 1220. In October 1225 an immense concourse of people assembled at the new city to dedicate three altars in the cathedral, and the bishop entertained several archbishops, bishops, barons, &c., at his palace. At this time the king had a palace at Clarendon, in the vicinity of Salisbury. A charter was granted by King Henry III., in the eleventh year of his reign, who therein states that he laid the first stone of the cathedral. "At this period an arrangement was made relative to the disposition of the buildings in the new city. The ground was divided into spaces or portions, each containing 7 perches in length and 3 in breadth, and these were again subdivided for the advantage of settlers." Such was the origin and first establishment of Salisbury, and that it was systematically laid out and regularly built may be inferred from the present arrangement of its streets. Differences and contentions, however, arose between the citizens and the prelate, the latter having paramount authority, and the former fancying that they could live and prosper better without ecclesiastical protection or influence. A year's trial convinced them of their error, and they again sought the aid and became subject to the bishop. In the time of Edward II., about 1315, they obtained a license to fortify their city with a rampart and ditch, and from remains of walls, &c., which were standing about a century back, it is evident that Salisbury was nearly of the same extent at the commencement of the fourteenth century as at the end of the eighteenth.

Greek Measures.

We have no ancient measures by which to determine the length of the Greek foot, but we have the general testimony of ancient writers that it was to the Roman in the ratio of 25:24. The Greek stadium, which contained 600 Greek feet, is said by Roman writers to contain 625 Roman feet, and also a Roman mile, or 5,000 feet, was reckoned equal to 8 Greek stadia or 4,800 feet; both of these calculations give the above ratio of 25:24. If therefore the Roman foot was 9708 of the English, the Greek foot was equal to 101125 English foot or 12135 inches. This value is confirmed by the measurement of the Parthenon. "Stuart," says Mr. Hussey, "measured the upper

step of the basement of the Parthenon, which is the platform on which the pillars stand, and is exactly that part of the building where we should expect that the measure would have been taken, if the name Hecatompodon was really given it on account of the dimensions. He found the width of the front to be 101 feet 17 inches, the length of the side 227 feet 7.05 inches, and since these two quantities are very nearly in the ratio of 100 to 225, he inferred that the two sides really contained these two numbers of feet. From this he calculated the value of the foot, from the front 12137 inches, from the side 12138 inches; of which the greatest exceeds the value given above by only .003 of an inch." Other measurements of the Parthenon and of other buildings at Athens tend to the same result. Strabo, however, quotes from Polybius a calculation which would make the Greek and Roman foot equal, but it is perfectly clear that there is a mistake in this statement. Plutarch again says expressly that the mile is a little less than 8 stadia, which would give a rather smaller ratio than that of 24:25 for the ratio of the Roman to the Greek foot. It is on the authority of this passage that Böckh gives the value above mentioned for the Roman foot. If, according to the supposition already noticed, a slight diminution took place in the Roman foot, this would account for the difference. But perhaps we ought not to consider this solitary passage of sufficient weight to influence the calculation. The Greeks used different standards at different times. The foot which generally prevailed over Greece was that by which the stadium at Olympia was measured, which was the one which we have been speaking of, and which was therefore the same as that used at Athens in her best days. Hyginus mentions this foot as being used in Cyrene under the name of Ptolemeius.

Duties of Clients.

It behoves an employer not to rush into building rashly. He must first feel a real and definite want and he must work out for himself the problem of what it is that he may with great propriety want. It would be obviously as ridiculous for a country clergyman in need of a modest parsonage house only to want a princely palace as for a nobleman of the highest social position and unbounded resource to propose to content himself with so humble a structure for his own accommodation and for the support in a fitting manner before the world of an hereditary dignity. Having clearly realised what it is that in the way of structure will best suit his needs and accord with his practical or æsthetic necessities, he must endeavour by comparison with what may have been done by others to ascertain approximately the probable cost of something like what he will require, and he will then be wise if he sets himself to provide the requisite funds, leaving a fair margin for contingencies of which he can form little or no estimate. It is at this stage that he will do well to select his architect, and he must look, if he would have his work satisfactorily done, almost as much for moral as for artistic qualifications. He should not call to his counsels a man of whom he cannot make a friend. He should with openness explain to the architect he may select his own views and necessities, but he should by no means be so far wedded to them as to be unwilling to receive, should it be necessary, a clear demonstration of any points of error of judgment into which he may have fallen with respect to them. On essentials, provided that they commend themselves to his reason as essentials, he should be entirely unyielding to his architect, within whose power it should be left to amplify or give an improved form to the supply of those necessities, but by whom the employer should never allow himself to be "talked out of" the omission of what he may consider to be indispensable to carry out the object for which he desires to call the structure into existence. It is this very reasonable firmness on the part of employers which forms the most valuable check against the possible domineering of an empiric. The possession of professional knowledge is always a snare to humanity and a temptation to dictate too arbitrarily. The architect himself is frequently under the domination of the traditions of his craft, and to give him a wise and clear programme in accordance with which he must frame his ideas of design is often to inspire him with the best elements for legitimate novelty and wise innovation upon effete precedent.

The Panathenaic Frieze.

When sculpture is only an agent, as it is in the frieze and other parts of architecture, its effects of chiaroscuro should become subordinate, and, like every other member, appear only as a co-operative part in the general effect of the whole building. This will be found to be the true reason for what may be thought the imperfect, inartificial mode of execution which was adopted in the bas-reliefs of the frieze on the Temple of Minerva at Athens. The figures which were intended to appear nearest the eye are inclining to the flat; they have, comparatively, the least convexity, and come off from their ground in a bold, square and detached way, with a rilievo similar to that of the triglyphs and pateras ordinarily used in those situations. Thus the lights being larger and less

broken, the whole appearance of those advanced objects is comparatively more preserved and distinct than the others, and the effect proper to the occasion is perhaps better obtained than it could have been in any other way. If these works were, from architectonic and optical considerations, solely calculated to produce their effect in a certain given situation distant from the sight, it can be no wonder, nor is it any imputation of want of skill in Phidias or his workmen, that they should appear very differently, and much wanting when brought near the eye into a situation the reverse of that for which they were intended. Had they been calculated for the panels of an arched way, almost on a level with the spectator, like those beautiful bas-reliefs in the Arch of Titus, there can be no doubt but that a style of execution directly the reverse ought necessarily to have been adopted, and would have been adopted, for the knowledge which influenced the conduct of the artist in the one mode does actually imply the cognisance of the other. This procedure, where the most advanced objects are kept comparatively flat, naturally produces a broad light on those advanced objects, with smart shadows or touches about the arms, eyes, nose and other associated projecting and engraved parts, which are relieved and well set off by the more interior figures, in consequence of their being more rounded, and thereby affording a greater quantity of middle tint and scarcity of light.

Protection against Fire.

There were persons at Rome, called matricularii, appointed on purpose to extinguish fires; and Du Cange says that they carried sponges with irons, and other iron instruments by which they could go from wall to wall and so extinguish the fire. He adds that the ama was a water vessel, used for putting out fires, mentioned by Juvenal and Pliny; but Holstein contends that the ama was a very large hook or grapple fixed at the end of long poles, such as are now used for extinguishing fires. A very old method of putting out fires was by cutting away with axes and throwing buckets of water; and this is mentioned both by Petronius and Gervase of Canterbury. Watchmen against fires were instituted by Augustus. It had before been the care of the ædiles. In the Middle Ages women used to fetch water in brazen pails to assist, and the pall of the altar was brought out. In 1472 a night bellman was instituted at Exeter to prevent fires and felonies; and in 1558 leathern buckets, ladders and crooks were ordered to be provided. It was also anciently usual to fine for houses or chimneys on fire; the students in universities forfeit their caution money. At Shrewsbury in 1664 it was ordered, for want of ladders, to take down May-poles and make some. The cry of fire occurs in Apuleius.

The Roman Lararium.

The Lararium was a place in the inner part of a Roman house which was dedicated to the Lares, and in which their images were kept and worshipped. It seems to have been customary for religious Romans in the morning, immediately after they rose, to perform their prayers in the lararium. This custom is at least said to have been observed by the Emperor Alexander Severus, who had among the statues of his Lares those of Christ, Abraham, Orpheus and Alexander the Great. This emperor had a second lararium, from which the first is distinguished by the epithet "majus," and the images of his second or lesser lararium were representations of great and distinguished men, among whom are mentioned Virgil, Cicero and Achilles. That these images were sometimes of gold is stated by Suetonius. We do not know whether it was customary to have more than one lararium in a house, or whether the case of Alexander Severus is merely to be looked upon as an exception.

Procedure at the R.I.B.A.

SIR,—The meeting at 9 Conduit Street yesterday evening was pre-eminently a characteristic one—redolent of the early days of the present Council, some time ago now—and worthy of its traditional treatment of Associates.

The Council and its followers came with the fixed determination, evident in every feature, to preserve to the bitter end an unruffled front. The third chairman of this one-subject discussion certainly gave little opportunity for a fair and square fight, and two or three of the old and well-tried sticklers for soft phrases and buttered adjectives turned up, after a somewhat prolonged and regrettable absence from the meeting-

room, to give him the benefit of their ancient experience in quelling turbulent spirits.

The case which I wish now to place before the profession is this:—

The Council brought forward certain resolutions with reference to the election of Fellows.

A question arose as to whether Associates could vote on those resolutions, having regard to Clause 28 of the Charter.

The chairman at the meeting of June 14 (page 393, *Journal R.I.B.A.*), after reminding Associates of Clause 28, ruled as follows:—That "if, however, when the report was put as a whole, they (the Associates) objected to any part of it, Associates could then exercise their right of voting against its adoption."

The *Journal*, p. 394, states as follows:—"The motion for the adoption of the report as modified was then put, and carried by a majority of 19—44 voting in favour and 25 against."

By-law 62 states, *inter alia*, as follows with reference to a resolution affecting a by-law:—"If the same be supported by a majority of at least two-thirds of those present having a right to vote and voting thereon."

Now, Sir, I contend that the ruling of the Chairman gave Associates the right to vote on the report, and they voted, the result being that the two-thirds majority required by by-law 62 was not obtained; 46 votes were required and only 44 secured. It can surely never be contended that when the Chairman gave his ruling he was trifling with the Associates, and proclaiming peace when there was no peace. Then the alternative is that the whole proceeding is null and void, and must be, to become operative, gone through entirely again.

It is this, of course, which the dear old Council cannot contemplate with equanimity; it is this which threatened to moisten the starch of the unruffled front, and it is this which we Associates should do our best to put right. Personally, I have no objection to placing in the hands of the Council the election of Fellows as they desire. I have, as I stated in the room, confidence in their integrity in that respect; but I protest strongly against this transparent desire to shuffle through a mistaken procedure.

Clause 33 of the charter terminates as follows:—"Provided always that no such by-laws (this includes alteration of by-laws) shall be of any force or validity whatever unless and until they have been approved by the Lords of the Most Honourable Privy Council."

What we have to do, therefore, is to bring formally before the Privy Council the facts of the case, and to ask that the request of the Council to add to the by-laws as they desire be not complied with.—I am, sir, your obedient servant,

13 Southampton Street, Strand: WM. WOODWARD.
July 13, 1897.

GENERAL.

A Universal Exhibition is to be held in Liège. The date has yet to be fixed.

A Party of Mexican archaeologists have, it is said, discovered Chinese inscriptions on the ancient monuments in the Magdalena district of Sonora. There is a Chinese tradition that 2,000 years ago an exploring expedition found its way to the west coast of Mexico.

A Discussion on "Architectural and Decorative Art in the Service of the Church," in which the Rev. W. H. Draper, the Rev. Dr. Cox, Sir W. B. Richmond, R.A., and Mr. R. Hallward will take part, is to be among the proceedings of the forthcoming Church Congress.

The Prince of Wales has presented the drawing *Summer Slumbers*, by the late Lord Leighton, exhibited last winter among his works at Burlington House, as an addition to the collection of sketches which have been secured for the nation, and which are now being hung on the walls of the late president's house in Kensington.

Mr. J. Wright, of Derby, has taken Mr. T. H. Tomlinson into partnership, and the firm will be carried on under the style of Wright & Tomlinson.

Mr. Charles Holroyd has been appointed by the Treasury to be Keeper of the National Gallery of British Art, the gift of Mr. Tate to the nation.

It is Proposed to erect a new porch at the south entrance to the Abbey church at Sempringham, near Billingborough, as a memorial to the Queen, who is lay impropriator of the parish and joint patron of the living. The ancient door, which is covered with ironwork, said to be of Danish origin, is in need of protection from the weather, and the proposed scheme will prevent its further decay. One feature of the new porch will be that a handsomely carved Norman archway, which was removed from the church many years ago, and used in the construction of a dovecote at Spanby, will be restored to its original position.

The Architect.

THE WEEK.

AMONG the addresses presented to the Prince of WALES at St. James's Palace as representing the QUEEN was one from the Society of Architects. It was accompanied by the President, Mr. ROBERT WALKER, J.P., of Cork, Mr. WALTER EMDEN, J.P., L.C.C., Mr. HENRY LOVEGROVE, A.R.I.B.A., Major F. S. LESLIE, R.E., Mr. EDGAR FARMAN and the honorary secretary, Mr. ELLIS MARSLAND. The address was as follows:—"The President and Council of the Society of Architects humbly approach the Throne that they may, with other of your faithful subjects, offer with profound respect their loyal congratulations on the celebration of the sixtieth anniversary of your accession to the throne of your ancestors. In your Majesty, as in your illustrious husband, the lamented Prince Consort, the arts have ever found a noble patron, and the Council is therefore emboldened to hope that your Majesty will graciously accept this humble address in the name of the Society of Architects. That it may please the Great Disposer of Events to prolong your Majesty's glorious reign, and to grant you every blessing, spiritual and temporal, is the fervent prayer of your Majesty's obedient and faithful subjects." The address had been illuminated under the superintendence of Major LESLIE. With it was a list of members, bound in vellum and gold, containing as a frontispiece a portrait of the president, Mr. ROBERT WALKER. The Prince handed the following reply to the deputation:—"On behalf of the Queen, my dear mother, I thank you for your loyal and dutiful address, and for the affectionate congratulations which you tender on the completion of the sixtieth year of her reign. It is a source of profound joy to the Queen to receive the expressions of devotion to her person and family which are offered by her subjects throughout the empire. She is gladdened by the thought that the sixty years of her reign have been years of progress in knowledge and of increase in prosperity. And she prays that, by the blessing of Almighty God, she may always live in the hearts of her loving and beloved people."

7 SOME important additions to the remains of Roman Chester have been made during the week. In the excavations for a new shop in Northgate Row the base of a large column was found in its original position. It is of native red sandstone and rests upon the natural rock, some 2 feet below the level of the present street, and almost in a line with the west side of Northgate Street, which some archaeologists have contended follows the line of one of the ancient Roman *vias*. The block is 4 feet 6 inches square, with a base moulding 15 inches thick worked upon it, and is in a good state of preservation. The diameter of the column is shown to have been 2 feet 10½ inches, or 3 Roman feet, of 11·6 English inches to the foot. A day or two after the base was discovered a column—if not the identical column belonging to this base, certainly one of the series—was partially unearthed. It is lying in a horizontal position a few feet from the base, with a modern party wall built across it. A few Roman coins, also in a good state of preservation, have been found upon the site. The columns which stood upon this and similar bases must have been equal to eight, if not nine diameters, or 24 or 27 feet in height, and there must have been at least two, but more probably four or even six, of them if, as appears likely, they formed the front of a Roman basilica or temple, and the building generally must have been of very imposing proportions. At present it is impossible to say whether these columns formed the east or west front of such an edifice.

ON Monday a case which should serve as a warning to architects was tried at the Bristol assizes. It was another example of how little value is now attached to one's acting as well as judging and experience dictate. The plaintiffs, ROGERS & Co., Limited, who are brewers in Bristol, opened a branch on the Power Estate, in Newport, Mon. Mr. WATKINS, the defendant, is an architect practising in the

latter place, and he was asked to estimate the cost of a new building. It appears he returned the sum as between 600*l.* and 700*l.* The actual cost of the building was 1,163*l.* 17*s.* The plaintiffs brought their action to recover a sum equivalent to the difference between the two amounts, viz. 463*l.* 17*s.* The defendant said he worked out the cost at 5*d.* per cube foot, and it made 674*l.* He found it ought to have been 7*d.*, which would be about 900*l.*, and he wrote stating this. He wrote the letter at his house, and the letter produced was the original from which he wrote the letter to the plaintiffs. No mention was ever made to him as to the limit to the price. He admitted he made a mistake in his first estimate. Mr. Justice DAY, who heard the case without a jury, said he was not satisfied that the defendant had informed the plaintiffs about the extent of the expenditure, and that was negligence. His lordship assessed the damages at 150*l.* Mr. WATKINS had claimed 56*l.* commission on the amount expended, but the sum was reduced to 35*l.* A verdict for 115*l.*, with costs, was, therefore, given for the plaintiffs. It will be observed that the defendant has been doubly punished. His commission was not determined by the amount of expenditure, and he has had to contribute a large sum towards that expenditure, as if he had bound himself that his estimate would not be exceeded. In fact, Mr. WATKINS had stated that a large amount would have to be met, but apparently the letter went wrong in the post.

THE Louvre will have to be furnished in order that it may be worthy of its reputation when the world visits Paris in 1900. M. REDON, the architect who was lately placed in charge of the buildings, has therefore an onerous task. The dome of the Pavillon Denon has become dingy owing to the neglect of the metal-work, and his operations have commenced with it. Within the building the escalier Daru, which has a chilling appearance at present, will have a new balustrade, although it may be only of cement and white marble steps for a part of its length. The Salle des Etats will be completed and rearranged. There will be a central salon assigned to the works of RUBENS, and fourteen smaller rooms branching from it, where Dutch and Flemish pictures will be exhibited. But when are we to see an English salon in the Louvre that will be worthy of its title, or, in other words, with examples of the best English masters?

THE annual excursion of the Surrey Archæological Society will take place on the 28th inst. The places selected for visits are Epsom, Walton-on-the-Hill and Banstead. Mr. J. L. ANDRÉ, F.S.A., will read a short paper on "English Lead Fonts" in Walton-on-the-Hill Church. The Roman villa at Chussex Plain and various small entrenchments or camps on the Heath will be examined. Banstead Church will be described by Mr. F. A. HEYGATE LAMBERT, F.S.A. Mr. RALPH NEVILL, F.S.A., will relate the history and associations of "The Oaks." A collection of pictures, books and other objects of local and historical interest will be exhibited at Garratt's Hall, Banstead. Mr. M. S. GIUSEPPI will read some notes on Burgh Heath and its connection with HUBERT DE BURGH. The programme promises an interesting day for archaeologists.

THE phrase "town and gown" does not suggest in England philanthropic enterprises. In Edinburgh "The Town and Gown Association" is a limited company having for object the erection of students' residences, workmen's dwellings and the like. The Association has existed only a year, but it does excellent service and has paid a dividend of 4½ per cent. to the shareholders. Whether the success is owing to the absence of an architect from the staff we cannot say, but it is unsafe to meddle with new or old buildings without the help of an expert, and the Association may have to pay dearly for its temerity in trusting to solicitors, bankers, auditors and secretaries for advice on constructional questions. It is claimed that experience in many directions has been acquired and economies in management have been introduced, but do the words signify that there is no need for an architect's services? It is said the whole organisation steadily progresses, and with the aid of increased capital a much greater and wider activity will be possible.

AN INVENTORY OF ANCIENT SCULPTURE.

ACCORDING to the reckoning of OBERLIN, there were at one time in Rome about 60,000 statues; BARTHÉLEMY did not hesitate to make the number 70,000, and later archæologists who have tried their hands on arithmetical calculations have arrived at more astonishing results. Believers in the power of Roman acquisitiveness will say the number is underrated. But if we assume that Rome does not now contain more than 2,500 examples of ancient art, which is a very liberal estimate, the question then arises, How has it happened that so small a percentage has been preserved? The invasions of the Eternal City will be said to be among the principal causes of the destruction, but barbarians were not likely to be more disposed than modern men to find a recreation in stone-breaking. There is generally more agreeable work awaiting conquerors, and more amusement would be found in the defacement of statuary than in demolition.

A little consideration will show how little reliance is to be placed on the estimates of OBERLIN and all who have followed him. In the sixteenth century there was a sort of official inventory of all the pieces in Rome which could be considered as examples of antique sculpture. The number was found to be 531. By adding the torsos and headless objects of any value, it was found there were in all barely 700 perfect and imperfect works to represent ancient art. Then followed continuous explorations, and many statues, busts and reliefs were discovered which had been preserved in the soil of Rome. But there were years which were not productive. Some of the treasure-trove was smuggled out of Rome and adorns other cities. But in all Europe and Rome it would be difficult to enumerate more than four thousand marble statues of any value. As for bronze statues, it is not easy to find a hundred of them. These facts will explain the cause of the monotony of museums of casts, as well as of the illustrations which appear in histories of sculpture.

We assume that repetitions are not to be counted. The ancients did not possess machines, but they held possession of industrious slaves, who were no less competent to produce copies. Works of that class are not worthy of figuring in a catalogue of sculpture. They are different from works which to the uninitiated may appear to be copies because they are evidence of fidelity to some antique type, and from the variations, however slight, we can measure the progress of evolution in the art. The crowd of direct or debased copies, the handiwork of mere journeymen, should be eliminated in any survey of sculpture in which excellence is an essential quality. These works are now to be found mainly in museums, for although the majority among them were intended for exhibition in the open air, they have become too precious to be left at the mercy of the atmosphere.

Our annual exhibitions, and the continual necessity of endeavouring to tempt amateurs to give commissions, have made sculptors productive, and as a consequence it is imagined that the ancient sculptors were the authors of numerous masterpieces. Modern writers who treat of sculpture have somehow a pleasure in always speaking of works in the plural, and in this way carry on a delusion. For it is astonishing how many sculptors have gained renown by one or a few works. The name of BATHYCLES of Magnesia is associated with a throne of APOLLO; HEGESIAS is known by figures of CASTOR and POLLUX; DAMEAS by a statue of MILO; ARISTOCLES by a group representing a contest between HERCULES and an Amazon. The fame of PTOLICHUS rested on a statue of a boy, and HIPPIAS is known only through a similar work. The chief work of CALLIMAKOS, according to some authors, was a Corinthian capital. All that could be related of POLYCLES was "Hermaphroditum nobilem fecit." Tradition did not ascribe to GLYCON any other work besides the Farnese HERCULES; MENOPHANTOS became celebrated by a copy of the *Venus of Troas*. Three sculptors gained renown through the *Laocoon*. It would be easy to refer to many other cases to show that quality rather than quantity was enough to captivate the Greeks. There were sculptors who no doubt executed several works, but of late years critics have grown sceptical of the records unless there is uniformity of quality or characteristics in each case. The fame of PHIDIAS is in consequence bedimmed, and he is supposed

to have been an inspirer of other sculptors rather than an executant, because of the multiplicity of works with which he is credited. There were many reasons for deliberation with the sculptors. The production of a noble statue was an auspicious event in Greece; the immortals were supposed to have some share in it, it had to sustain public criticism, and the author was liable to pains and penalties if he were considered to have erred against the sacred traditions. The Greek sculptors would have been happy if there was no more severe tribunal than is made up by modern newspaper critics. From all we have said the scarcity of masterpieces may appear less remarkable. The Greeks were not compelled to make money as expeditiously as is now the case; they could wait for inspiration to arrive and they had confidence that their countrymen were able to appreciate niceties in form and arrangement which would be unobserved by eyes less keen and instructed.

But if masterpieces are less numerous than is commonly supposed, what is to be said about those which are unrestored or have no need of restoration? That is a subject which by a tacit agreement is avoided. If the rule which is sometimes recommended to architects in restoring buildings were applied to sculpture, that is, by making additions and alterations manifest to all observers, every collection of ancient sculpture would become a horrible sight. Fancy all the reparations in yellow or blue or other colour which would make the process plain to the simplest rustic. All those rigorous censors who are so opposed to restoration that, like Alderman CUTE, they appear to have resolved to "put it down," forget that the office of art is to give pleasure, and as people do not care for acrobats with wooden legs or arms, although performers of the kind find temporary acceptance from their novelty, we cannot expect them to delight in maimed buildings, statues or pictures.

As people do not comprehend either the number of ancient masterpieces which have survived or the extent of the restorations, it would be an advantage if an impartial survey of the sculpture galleries in modern museums could be prepared. Something of the kind was attempted by MÜLLER, but it is not a task for an individual. A lover of sculpture is sure to be carried away by human weakness, and will over-estimate or under-estimate the value of a work according to his mood. In the same way the officials of a gallery are apt to believe that there is some connection between their dignity as compared with officials elsewhere and the works they have in charge. Hence it is that so little reliance is to be placed on the catalogues prepared by them. What is needed is some inventory which would embody the conclusions of a sort of international jury, and which could be accepted as representing the results of investigations which have been in progress since the sixteenth century. If all the examples which can be considered as having qualities which are worth appreciation were photographed from several points of view and copies attached to the inventory we should then have a clue to the signification of ancient sculpture which is not afforded by the histories or catalogues which are now employed as guides.

ELECTRICAL DISTRIBUTION SYSTEMS.

THIS subject is becoming one of great importance to borough engineers, and, in fact, to all the officials connected with municipalities that are introducing or considering the introduction of electric lighting, and there are many points upon which engineers and surveyors can render great assistance to the electrical engineer, that they should endeavour to become acquainted with. One of these points which may be mentioned is the construction of underground transformer chambers.

The above subject was brought before the Municipal Electrical Association at their annual meeting by Mr. J. A. JEKELL, borough electrical engineer, South Shields, and also by Mr. J. A. BLAIKIE, chief assistant electrical engineer, Bristol. Mr. JEKELL deals with principles chiefly, Mr. BLAIKIE with details, and in the latter there are many points of interest in connection with underground boxes and sub-stations.

Considering Mr. JEKELL's paper first, we find at the very commencement a point which is pressing itself more and more to the front. The matter refers to

tenders and specifications in connection with local authorities. The question of the lowest tender is brought up, and Mr. JEKELL says that the lowest tender is not the best to accept, but the one which in the opinion of the engineer offers the best value for money, irrespective of the amount of tender. Mr. JEKELL, it seems to us, has supplied the retort to his own contention when he says, "Thus we find every reason why there are likely to be as many different opinions about systems as there are engineers, and even more, because it may happen that an engineer may be an advocate of one system to-day and another a short time hence." It appears from this then that the judgment of the borough engineer is not so very trustworthy, and is, to say the least of it, rather arbitrary. What, then, is the remedy for the complaints of contractors who have had their tenders rejected on the personal preference of the engineer for another contractor's system?

It is certainly very unfortunate that this personal preference should be allowed to reject on principle a tender which comes within the specification. If a borough engineer (electrical or otherwise) wishes to exclude certain systems or plant, the specification should be drawn up definitely to do this; but to issue a broad specification, invite tenders, and then only consider the one which the borough engineer prefers is certainly a very doubtful proceeding. It opens the way for much corruption and scandal, and will shake the public faith in the author. From another point of view it is advisable to draw up strict specifications. Contractors have plenty of preliminary expenses without putting them to the trouble of preparing estimates when it has already been decided to reject them, whatever the price. Such rejection often entails a quite unjust loss of reputation, and also as a firm has to prepare useless tenders it must raise its price to make up for the increased expenses. If a specification is properly drawn up, and the engineer knows and is not afraid to say what he wants, the lowest tender is surely the best, unless the firm is one which is known to shirk its responsibilities.

The author rightly says that no one would use high tension when he could use low, and the higher limit of pressure now allowed by the Board of Trade for low-tension systems (220 volts) will, he says, doubtless come into more general use, especially on account of this pressure being suitable for traction work, the combination of which with central stations is becoming one of the foremost characteristics of municipal electrical supply. The greater simplicity and reliability of the low-tension system, the fact that accumulators can be charged, and that the motors are better, all have an effect on the load factor and economy of the station.

The high-tension direct system is recommended as being good for reaching outlying districts which are in themselves fairly compact.

The high-tension alternating system is, of course, recommended for scattered districts, and but for this system many places now enjoying the electric light would be in darkness.

Whenever alternating current systems are used the question of sub-stations comes to the fore, and some space may be devoted to it, as it is of interest. The essentials of a good transformer chamber or sub-station are that it shall be dry, well ventilated and not subject to condensation of moisture from the atmosphere. Mr. JEKELL considers that if the transformers are to be underground, they should be placed in iron cases direct, and we feel inclined to agree with him. As the author correctly says, the system is beautifully flexible, economical and cheap, while it is eminently safe.

The combination of accumulators with alternating-current systems is advocated as being a means of improving the load factor. Mr. JEKELL further investigates the losses in the mains with various systems, and also the systems of mains. A very practical point, and one of great importance, is that "a cable, however good, may be irretrievably damaged by being badly laid and badly handled, and many of the faults which are put down to faulty manufacture are really due to bad laying. Gentlemen who have not had much experience in cable laying seem generally to think that anybody can lay a cable. Everyone who has had a wide experience, however, knows that this is a very erroneous idea." This passage from a man of good experience shows the necessity of those not specially trained to engage com-

petent electrical engineers to undertake their electrical work. They may have a general knowledge of the subject, but not sufficiently practical one.

Mr. BLAIE, in his paper, as before mentioned, deals more with details than principles, so it need not be dealt with so fully, although to the electrical engineer it is of the greatest interest. It is with details that electrical engineers are now mostly concerned, the principles having already been fairly fought out, at least for the present. Mr. BLAIE very rightly points out that overhead wires should be permitted by the Board of Trade, especially in small country towns, as they would enable a supply to be given when otherwise it would be impossible owing to the cost.

A very useful table is compiled, showing the proportions of various cables in use in Great Britain. Twenty-two stations use bare copper mains, 38 india-rubber, 8 bitumen casing, 8 solid bitumen and 56 lead-covered and armoured. The great increase in the use of lead-covered cables for mains is commented on and the reasons discussed. These reasons are chiefly that they have been found to be reliable and cheap, and we look for a still further extension of the lead-covered cables for all electrical work.

The author goes very fully into the question of transformer pits or sub-stations, and says:—"The first difficulty is to make such receptacles or chambers watertight, the next to insure their being free from gas, either leakage from gas mains or the explosive product of electrolysis; and thirdly, to keep hygroscopic insulators or walls from falling below the temperature of the air. Moisture in air does not matter unless it deposits." Here is a problem which we can commend to architects and borough surveyors. Any one who can comply with the above conditions and the condition of cheapness will earn the gratitude of electrical engineers. Various modes of construction are mentioned. "The commonest plan is to build double walls, have a space of from 1 to 2 inches in between filled with hydraulic cement, bitumen or pitch. In some instances these walls are 4½ inches and others 9 inches. Chambers about 7 feet by 7 feet by 6 feet inside of this type cost from 50% to 60%. Puddled clay outside the walls has been used, but the cost is not given.

"Cement concrete, having asphalte lining, costs about 70%; cement concrete, heavily faced with cement only, 28%; good dense bricks, laid in cement 18 inches thick, cost about 65%. One of the latest methods and the cheapest is the use of concrete with glazed tiles, having an L-shaped section. A glazed surface with fine cement joints makes an ideal watertight structure; the cost is about 25%." The author points out that the roof is an important detail, as the changing differences of temperature between the inside and outside tends to make the roof "sweat." A brick arch has the advantage that the water runs down the sides instead of on to the apparatus. The use of wood in a roof is recommended. "With a view to keeping the roof dry, independent of ventilation, some roofs have been constructed in the following manner:—One-inch flooring boards treated with creosote are laid on 2-inch by 3-inch joists (wood), over this is laid sheet roofing lead with soldered joints quite flat, and the edges well over the outside of the walls. Sand to a depth of 2 inches is laid over the lead and then iron joists and concrete. The wood being non-hygroscopic keeps the inside dry. It could not do any external damage if by any extraordinary means it should take fire." Artificial ventilation is condemned, as the heat of the transformers should be sufficient. The best ventilation is by means of two pipes led to about 6 inches above the pavement level, one from the top and the other from the bottom of the chamber. Tables are given showing the differences of temperature actually existing, the greatest being about 35 deg. F.

The rest of the paper deals with purely technical matters of interest only to central station engineers, and need not be discussed here.

H.E.H. the Princess Louise (Marchioness of Lorne) opened the new buildings in connection with the Grosvenor Hospital for Women and Children, Vincent Square, Westminster, on the 21st inst., to which new special hospital and out-patients' department Messrs. Roumieu and Aitchison are the hon. architects.

CANTERBURY CATHEDRAL.—IV.

CANTERBURY CATHEDRAL continued to be a part of "the Priory of Christ Church" until the sixteenth century. Unlike most of the monastic establishments, it was not suddenly suppressed in the reign of HENRY VIII. There was a show of method in the transaction. The procedure adopted was curious. First, certain festivals which were celebrated in harvest-time were prohibited. Then the Feast of St. THOMAS was abolished. A year or two afterwards, by the King's orders, he was declared to be unworthy of being considered one of the saints, as he had been unfaithful to his king. As a consequence, his images and pictures were ordered to be removed from all churches. The degradation of the patron was followed by proceedings for the dissolution of the priory. A commission was formed, consisting of nine members, who were directed to take possession of the monastery, to make an inventory of all goods, chattels and other property, and to remove all jewels, plate and money, which were to be surrendered to the master of the jewel-house in the Tower of London. From the time of LANFRANC, the prior of the monastery held a position that was similar to the dean in other cathedrals, but after the dissolution a chapter was organised.

The cloisters, without further evidence, would be enough to prove the connection of a monastery with the cathedral. What we see are among the works constructed in the beginning of the fifteenth century. Probably they are on the site of the early cloister along which BECKET walked to his doom. His aim was to die at the high altar in the choir, and he would not listen to those who suggested that he should seek safety in the crypt. Accordingly, he would not allow the doors in the cloister to be secured against his foes. Having passed along the cloister and through the transeptal chapel he ascended the steps towards the choir. But when he heard the knights calling for the traitor the archbishop came back and met them in the chapel. He stood against a pillar which no longer exists, and there he died.

The vaulting of the cloister is elaborate, and when the seven hundred shields were emblazoned in proper colours must have offered a fine spectacle to all lovers of heraldry. The system of construction, although it appears to be intricate, is considered by Professor WILLIS to exhibit as little system as a spider's web, and yet the effect, he acknowledges, is after all rich and peculiar. The Professor gives the following account of the system employed:—

The mechanical construction of these lierne vaults is various. Most of them, at least the larger and simpler examples, are built exactly in the same manner as rib vaults,

that is, a stone framework is constructed of ribs, liernes and boss stones, all of which are rebated for the reception of stone panels or vaulting surfaces, which are dropped in from above. When the vaults are large and the ribs and liernes few, these intermediate surfaces are built of light rough masonry as before; but when the intervals are made smaller by the increased number of the reticulating ribs and liernes, the connecting surface becomes a mere panel of one or two stones, each of which was probably scribed, as a carpenter would call it, to fit the frame. An example of this method from the cloister of Canterbury Cathedral is shown.

The span of this vault is 13 feet, the ridge ribs are level, and it approaches in effect very near to a fan vault, although it is not one. In fact, the middle plans of the spandrel, instead of being circles round the impost A, as in fan vaults, are of the figure B, C, D. The *tas de charge*, or portion of masonry above the impost which contains the nascent ribs in their state of entanglement, is laid in three courses, of which the lower is 2 feet 6 inches in thickness and the others 1 foot 3 inches and 9 inches respectively. The upper stone has inclined beds formed for each rib to spring from, and the plain portions of rib which connect this stone with the boss stones in the crown of the vault are built of voussoirs, about 18 inches more or less in length. The bosses are so numerous and lie so close together that the stumps of ribs that are in one piece with adjoining ones touch for the most part, as shown in the drawing, with one or two exceptions, where small thin slices of rib are interposed; these are marked *m* in the figure. Some of the compartments are foliated, but the cusps are attached to and worked out of the boss stones. The panels are laid in in one or two pieces, as the case may be. Their joints, which occur irregularly, are indicated by dotted lines. In this and similar examples the stumps of ribs which spring from each boss stone are worked separate as so many branches. This is shown at the margin of the figure. In other vaults of this class, however, the boss stones are so worked that they each contain a portion of the panel surface between the short ribs.

Not the cloisters only would be strange to the eyes of the martyred archbishop, but it may be doubted whether, with the exception of a part of the crypt, one stone remains which he could have observed. In the course of the works which were carried out from time to time some of the old stones were likely to be utilised, but it would be in places where they were not too apparent. The monks would endeavour to suggest how well they had applied donations in a new creation.

After the completion of the choir there was a period of nearly two centuries which was not signalised by the erection of any important work. Then there was another century in which several of the most interesting parts of the cathedral were undertaken, including the transepts, the cloisters, the south-west tower, the nave, the chapel of HENRY IV., the lady chapel and the central tower. For those works there was no second GERVASE in the monastery to relate for the benefit of future ages the progress of the workmen. Such an account may have been prepared, but it perished with other documents at the dissolution. Building had become more scientific, and an account by an onlooker would be a most valuable source of information. All that the study of various detached documents could produce has been presented by Professor WILLIS for one part of the work, but it must always be regretted that neither his industry nor the labours of other archaeologists can fill up the voids. He says:—

In December of the year 1378, Archbishop Sudbury issued a mandate addressed to all ecclesiastical persons in his diocese enjoining them to solicit subscriptions for rebuilding the nave of the church, and granting forty days' indulgence to all contributors. The preamble states that the nave, on account of its notorious and evident state of ruin, must necessarily be totally rebuilt, that the work was already begun and that funds were wanting to complete it. In the year 1397, Archbishop Arundell appropriated to the convent the parsonages of Godmersham and Westwell, in Kent, at their petition. The preface to the instrument of appropriation (dated in the above year) expressly states the reasons for this grant to be that "Simon of Sudbury, formerly Archbishop of Canterbury, and our predecessor, had caused the nave of our church to be taken down to the foundation and demolished at his own expense, for the purpose of re-erecting the same, as he intended and fervently desired to do, but was prevented by his violent death on June 15, 1381 (he was murdered on Tower Hill by some of Wat Tyler's men); and that the prior and convent had laudably expended upwards of 5,000 marks out of their common property upon the construction of the said nave and other necessary

works about the church. Also, that 6,000 marks would be too little to finish the work as begun, and others that must be done about the prostrate cloister and the chapter-house, which is thought to be in a dangerous state;" and he also states as a reason for thus augmenting their funds, his wish that so laudable and necessary a work should be carried on, lest its final completion might be retarded "by the loss of the present prior," or by other adverse circumstances.

In the obituary it is recorded that Archbishop Courtney gave more than 1,000 marks to the fabric of the nave of the church, the cloisters, &c.; and that Archbishop Arundell gave five sweet sounding bells, commonly called "Arundell ryng," as well as 1,000 marks to the fabric of the nave.

Of Prior Chillenden, the same document states that "he, by the help and assistance of the Rev. Father Thomas Arundell, did entirely rebuild the nave of the church, together with the chapel of the Blessed Virgin Mary, therein situated, and handsomely constructed." Also the cloister, chapter-house and other buildings enumerated.

The epitaph of this prior, preserved by Somner, confirms this statement by saying, "Here lieth Thomas Chyllindenne, formerly Prior of this Church . . . who reconstructed the nave of the Church and divers other buildings . . . and who, after holding the priorate twenty years, twenty-five weeks and five days, completed his last day on the assumption of the Blessed Virgin (Aug. 25), A.D. 1411."

The history of the nave resembles that of the choir of Elnulf in this respect, that the archbishops assisted the work with funds and influence, but that it was really carried on by the convent under the immediate direction of the prior. It is not even certain that the prior was the actual architect in either of these instances; for in those times, as in our own, men in high official situations were to be found who took the greatest pleasure in promoting the erection of buildings, and assisted in the carrying on of the works in various ways, by advising, criticising, furnishing funds and cheering on the proceedings by continual countenance and sanction. And to such men the credit of the enterprise may very justly be attributed, but not the credit of the design artistically speaking. This was often due to some obscure monk, or workman, whose name has been lost. For example, Matthew Paris records that a new roof was formed of oak for the aisles of the church of St. Albans, as well as for the tower, and substantially covered with lead, all which was done at the instigation and by the labour of Michael of Thydenhanger, monk and camerarius. Nevertheless, he adds:—"These works must be ascribed to the abbot out of respect to his office, for he who sanctions the performance of a thing by his authority is really the person who does the thing." This doctrine, however true it may be in the sense in which the author intends it to be taken, is fatal to the history of art; for it has been largely acted upon by the monkish chroniclers, who attribute architectural works, without reserve, to the bishop or prior whose biography they are writing, when in reality these labours were carried on by the monks and directed by artists whose names, with few exceptions, are lost.

The nave, transepts and pillars of the central tower of Canterbury all evidently belong to the same period and constitute one work, for they are all in the same style and of the same design (except, of course, the buttressing arches and additions to the tower piers). The work of the nave, therefore, above mentioned, must be held to include these transepts. The documents just quoted, which in fact contain all that is known upon the subject, have told us that Archbishop Sudbury pulled down the nave about 1378 on account of its ruinous condition, intending to rebuild it, but was prevented by his death in 1381, and that the succeeding archbishops, Courtney and Arundell, contributed largely to the funds. Prior Chillenden, who held that office from 1390 to 1411, seems to have been the most active person in conducting these and other buildings, and is thus alluded to in the Arundell grant.

This grant is dated in the second year of Arundell's archbishopric, and the seventh of Chillenden's priorate, and the works seem then to have been in a great state of forwardness, but our information fails to give us the real architect or the exact year at which they were commenced, and from which the design must be dated. Nine years intervened between the death of Sudbury and the beginning of Chillenden's priorate; but he may have conducted the works in the meantime in some other monastic office.

When the rebuilding of the nave and transepts was undertaken the portion they were designed to replace was the original nave and transepts of Lanfranc; this was considerably lower than the eastern church. Now in the nave the whole of Lanfranc's piers, and all that rested on them, appear to have been utterly demolished, nothing remaining but the plinth of the side aisle walls. In the transepts more parts of the Norman walls were allowed to remain, especially on the eastern side and at the angles; and of the tower piers the western are probably mere casings of the original, and the eastern certainly appendages to the original. But of course it must be under-

stood that I have no evidence to show how much of Lanfranc's pier was allowed to remain in the heart of the work. The interior faces of the tower walls appear to have been brought forward by a lining so as to increase their thickness and the strength of the piers with a view to the erection of a lofty tower, which, however, was not carried above the roof until another century had nearly elapsed.

THE BRITISH SCHOOL AT ATHENS.

ON the 15th instant the annual meeting of the British School at Athens was held. Sir E. J. Poynter, P.R.A., presided. The report of the managing committee stated that, in spite of the recent war, the school had had a very satisfactory session. The number of students had been considerably above the average, and good work had been done both at home and in the field. The students' hostel, to which reference was made in last year's report, had now become an accomplished fact. The total cost of the building would probably be about 1,500*l*. The subscriptions to the building fund amounted to rather more than 1,000*l*., and the committee invited further aid in order that the scheme might be carried through without trenching upon the ordinary funds of the school. In the winter and spring the excavations begun last season on the supposed site of the gymnasium of Kynosarges in Athens were carried to completion. The cost of this undertaking had been met by funds provided by private friends. After various difficulties and delays, work was resumed in Melos on the site of Phylakopi early in May, and carried on energetically for four or five weeks. There was now no doubt that the remains of an important prehistoric city had been discovered, the complete excavation of which, in a subsequent session, might lead to results of first-rate interest. The school being now in a position to plan its work in advance, the committee had under consideration several schemes for further excavation. The number of the school annual recently issued contained papers which might be regarded as permanent contributions to archaeology or to history. In the course of the session considerable additions had been made to the library, especially in the department of travel, which was intended to form the special feature of the collection. The sale of the library of the late Professor Overbeck enabled the committee to acquire some books of special value and interest, and the committee had been in negotiation with the executors of the late Mr. George Finlay for the purchase of at least a part of his valuable library. The leave of absence granted by the trustees of the British Museum to Mr. Cecil Smith had now unhappily expired. It had therefore been necessary to look for a new director. The committee had been fortunate enough to secure, for three years at any rate, the services of Mr. D. G. Hogarth, Fellow of Magdalen College, Oxford, a former student of the school, and well-known as an explorer in Asia Minor and Egypt. The committee had to regret the loss of one of their number, Mr. Theodore Bent. To the seat thus left vacant Professor Ernest Gardner, formerly director of the school, had consented to accept nomination. Mr. George Macmillan, who had acted as honorary secretary of the school since it was first opened in 1885, had found himself reluctantly obliged by increasing engagements to resign the office at the end of the current session, though still willing to serve upon the committee. The committee expressed their regret at the loss of Mr. Macmillan's invaluable services. Mr. William Loring, one of the most distinguished students of the school, had consented to take up the work. The committee had to announce that the Government grant of 500*l*. a year for five years was duly ratified by the House of Commons before the end of last session, and the first instalment had been received. But the present resources of the school were barely sufficient to carry on the work on the present scale. The committee saw no reason to be dissatisfied with the results of the past session. Indeed, it might be doubted whether during this particular year any other foreign school in Athens had got through so much. So long as the school had no permanent endowment it could not enjoy entire freedom of action. It behoved, therefore, all friends of the school to keep its claims and requirements continually before the public.

The Chairman moved the adoption of the report. The necessity of preparing the Gallery of British Art, shortly to be opened, and other engagements had prevented him from preparing an address which should be worthy of such an audience. His interest was naturally on the purely artistic side of Greek archaeology, and in that respect he would be glad to give such help as he could. He earnestly pleaded for assistance for the school, which was not so much competing as co-operating with the richly-endowed schools of other nations. The school owed much to Mr. Smith's indefatigable labours. The hostel would be a great boon to students, and Mr. Smith's work in raising the funds deserved their gratitude. Excavations were the life of archaeology, and it was to be hoped that the funds of the school would enable it to purchase land in the city itself from which valuable results might be hoped. Students had the

advantage of attending the lectures not only of this but of other schools, and Athens might thus become the seat of a university of archaeology.

Mr. Percy Gardner seconded the resolution, and made warm acknowledgment of Mr. Macmillan's services.

The resolution was unanimously carried.

The director (Mr. Cecil Smith) then read his report, in which he said that the political troubles and, still more, illness—and especially that of Mr. Bosanquet—had seriously hindered their work. But good work had been done, and the school was more numerous than any of the other schools. Some good finds had been made at Patras, especially a statuette of Athene, of singular interest and beauty, which might safely be attributed to the third century B.C. It was hoped that the labours of the students, in the islands particularly, would be rich in discovery. Each student had his own sphere of research. They had also found important traces of a town of the Mycenaean period, and a bronze statuette of the same age. The new law applicable to excavations made the outlook for archaeologists of the future very grave, and could not but operate injuriously to the cause of archaeology.

The proceedings concluded with the usual votes of thanks to the director and the chairman.

SUSSEX ARCHÆOLOGICAL SOCIETY.

ON Tuesday last a very large number of members of the Sussex Archaeological Society attended the annual excursion, when some places in the neighbourhood of Worthing were visited. Although the district is known to strangers, it has been rather neglected by the Council of the Society. In the first half-century of the Society's existence there was only one visit, which was twenty-three years ago.

Sompting Church.

The first building selected was Sompting Church, which was described by Mr. J. Lewis Andre. The interesting character of the building had been duly acknowledged, he said, by many eminent authorities on church architecture, and there could be but one opinion as to its value as an example of very early work. The name was recorded in Domesday Book, and the parish was said to have a church and five servi or serfs, whom Horsfield erroneously termed ministers. In 1154 William de Harcourt and William de Braose gave the impropriate to the Knights Templars, and on the suppression of that Order it passed through Sir Andrew Peverell to the knights of St. John of Jerusalem. After the dissolution of monasteries, the living passed through several hands into the possession of the Barker family, and then into that of the Crofts, who still held it. The registers dated from 1546. The tower was in all probability erected just before the Conquest or early in the eleventh century, while the nave and chancel were of twelfth-century date. North of the tower were ruins of a chapel of fourteenth-century work, and in the fifteenth century the earlier features were to some extent obscured by the introduction of numerous windows of the Perpendicular style. The spire was unique in having all four sides gabled, and in ending in a pyramidal roof. An interesting feature of the interior was a tomb identified by Lower as that of Richard Burre, who, in his will of the 19th of Henry VIII., styled himself "farmer of the parsonage of Sountynge, called the Temple," and ordered that his body should be buried in the chancel of the church, and that his obit should be kept for eleven years, and 12s. 4d. spent on these occasions on priests, ringers, clerks, and "pouer people." The monument bore the arms of the Fishmongers', Leathersellers', and Goldsmiths' Companies, with those of the Tregoz family. It was also an interesting fact in connection with the parish, that in 1262 the manors of Cokeham and Stanham were rented for a pair of white gloves.

Broadwater Church.

At Broadwater Mr. Andre again served as cicerone. He pointed out, in the first place, the curious distribution of the parish, parts of which were to be found as far north as Horsham and Midhurst. Domesday Book, he said, informed them there was a church at Broadwater and three servi, and the registers commenced as far back as 1558. He explained the architectural features of the building, and called attention to the handsome brass to the memory of John Mapleton, a rector, who died in 1432. The chancel tomb of Thomas Lord la Warre, who died in 1526, was the finest specimen in Sussex of an Easter sepulchre tomb. It was described as a Gothic tomb with Renaissance details. The decoration included the initials "T. G." in a love-knot, and the crampette, or end of a sword sheath, which was the famous badge bestowed on an ancestor, Sir Roger la Warre, for valour on the field of Poitiers, when, with the help of another Sussex worthy, Sir John de Pelham, the French king was made captive. Another fine tomb was that of Thomas Lord la Warre the younger, who died in 1554.

West Tarring Church.

After luncheon there was a visit to West Tarring Church. Mr. J. Lewis Andre said the first notice of West Tarring was in a record stating that before the year 944 it had been granted

by King Athelstan to the Church of Canterbury. Its possession by the Archbishop of Canterbury was mentioned in Domesday Book, from which it appeared there was a second church at Heene, dedicated to St. Botolph. The earliest portion of the present church dated from the thirteenth century, and the building contained a valuable example of a low screen of Mediaeval origin. The churchwarden's book contained some curious entries, among them being one in 1556 "for making Mary and John and Sent Aundero, 21d." The church was thoroughly restored in 1854 at a cost of 4,000*l.* The remains of the palace of the Archbishops of Canterbury were also visited.

A Saxon Cemetery.

Lastly, came the visit to the Saxon cemetery on Highdown Hill, discovered and excavated by Mr. Edwin Henty, J.P. The cemetery lies within the encampment, and the *Sussex Daily News* says that already 120 interments have been found. The skeletons lie east and west, and are discovered by means of trenches dug in the transverse direction, and though the bones are very fragile, and sometimes imperfect, there have been some valuable finds in the shape of weapons glass vessels (supposed to have been even in those remote days "made in Germany"), fibulae, buckles and ornaments of various descriptions. Mr. Henty has taken great interest in the work of investigation, and has a fine collection of these articles at his house at Ferring. The graves are about 3 feet 6 inches in depth, and the period of interment is supposed to have been from the sixth to the ninth century. The first grave opened on Tuesday proved a blank, but at a second excavation the removal of a few shovelfuls of earth and chalk laid bare the arm bones of a skeleton. Search was then made near the skull for the drinking cup and other articles sometimes placed there, but nothing was found, and the skull bones themselves had to a large extent disappeared, leaving little besides a handful of teeth. On the breast of the skeleton was a small brass fibula of a rather interesting character, on which could be distinguished some ornamentation, in the form of circles. There was also found in this grave a piece of rusted iron, which had been either a buckle or fastening of some kind, and the blade of a knife, the handle of which had altogether vanished. A third grave was opened, but gave up nothing but bones, and a small flake of iron rust, which, from the position in which it was found, was thought to have been once a knife.

A vote of thanks was passed to Mr. Henty for the trouble he had taken. The party then drove to Ferring, where they were allowed to inspect the museum of articles found at Highdown.

PUBLIC LIBRARIES.

AT the Conference of Librarians on the 15th inst. Mr. F. J. Burgoyne, librarian, Public Libraries, Lambeth, read a paper on "Public Library Architecture from the Librarian's Standpoint." He treated chiefly of the internal arrangements of library buildings. The problem was different according to the means at the disposal of the authorities. The rooms should not be too large; two or more of a smaller size were better than the same area in one room, as small rooms were less draughty and warmer. Books should be accessible without ladders; the windows should be high, the ceiling lofty, the lighting good and well distributed, skylights should be double so as to prevent the access of the direct rays of the sun, and the windows should be double where there was much traffic. If gas was used ventilating shafts should be provided to carry away the fumes, and some form of incandescent gas should be employed. The Aberdeen Public Library was a model of what such a library should be.

Mr. Crunden, Dr. Justin Winsor and others expressed their opinions on the most desirable appliances for heating, ventilating and other matters. The chairman (Lord Crawford) gave an account and criticised the lighting and ventilation of the Houses of Parliament.

The Chairman announced that M. Delisle, the principal librarian of the Bibliothèque Nationale, Paris, had presented through M. Omont a copy of the first volume of the great printed catalogue of the library which had just been published. It was estimated that this vast undertaking would extend to about 150 volumes, which would be printed as soon as the demand of the public made it possible.

Mr. Beresford Pite, F.R.I.B.A., subsequently dealt with the question from the architect's point of view. A good collection of books, he urged, deserved a good building, as a good book deserved a good binding. Dignity, simplicity and restraint should be the main features of a library, and in the rooms ornament should not distract attention from the books.

Sir H. Howorth, M.P., said the question was, Are the books meant for the library or the library for the books? In his view the librarian ought to arrange his books, whereas generally a library was intended mainly to glorify the architect. Smirke's room at the British Museum was an admirable example of the adaptation of a room to its use.

Mr. Dewey said the most conspicuous failures had been the libraries at Boston and Chicago, on which a mint of money had been spent. In designing a building the best thing would be to compile a list of things to be avoided, and if such things were avoided the best conceivable plan would be found in the residuum.

Dr. R. Garnett said that to him many years ago an empty shelf was a much more beautiful object than a full one, for he had no place for the ever-accumulating mass of books. But now he had not the same satisfaction at unoccupied space which he used to feel, for the sliding press had, in the economy of space effected, been a veritable boon to the librarian. It would be a good thing if the architect would subordinate all æsthetic considerations to practical requirements, and would make his plans not only for the present, but for the future.

THE FRANKS' BEQUEST.

THE personal estate of Sir Augustus Wollaston Franks, late Keeper of British and Mediæval Antiquities in the British Museum, who died on May 21, aged seventy, is valued at 118,670*l.* net. A codicil to the will has the following bequests:—"I bequeath to the trustees of the British Museum all collections lent by me on loan to the said Museum or to any other museum or exhibition, my collection of finger rings and personal ornaments of olden times, and any of the curiosities or works of art in my possession at the time of my death, which the said trustees may please to select, excepting oil and water-colour paintings, prints, and books and manuscripts not specifically bequeathed to them. I also bequeath to the said trustees my collection of book plates (*ex libris*), trade cards and tickets, together with my catalogues of the same, and such books as I have indicated by a note in them as belonging to my said collection of book plates, and I request that the said collection, catalogues and books may be placed in the Department of Prints, and that the book plates may be kept together as such, and not distributed under the engravers' names, except in the case of duplicates. I further bequeath to the said trustees such of my books on pottery and porcelain as are not already in the library of the Department of British and Mediæval Antiquities, to be added to the said library. And as to these bequests to the British Museum I desire my executors to apply to the Government for a remission of probate duty with respect to them. And if this be not granted I declare my said bequests to the trustees of the British Museum to be null and void, and I desire and direct that the objects which would otherwise have passed to the British Museum be sold by public auction and the proceeds added to my general residuary estate." Sir Augustus Franks bequeathed to the Society of Antiquaries of London, of which he was president, such of his printed books on antiquities, art, history and genealogy as are not already in the library of the said Society, together with his heraldic manuscripts and any of his drawings and engravings of ancient seals which the Society may desire to possess.

CHRIST'S HOSPITAL, HORSHAM.

IN the House of Commons on Monday Mr. Giles asked Mr. Grant Lawson, as a Charity Commissioner, whether the bills of quantities for the school buildings of Christ's Hospital on the new site at Horsham had been completed, and, if so, whether they exceeded the estimate; whether the expenditure of 20,000*l.*, sanctioned by the Commissioners for the work of draining roads, levelling and planting, was now expected to be insufficient owing to the soil being so deep and strong a clay; whether, since the acquisition of the Horsham site, the number of scholars had considerably decreased, and, if so, to what extent, and if the governing body had been obliged to sell stock to meet the current expenses of the school, and, if so, to what amount; and whether, having regard to the great interest taken by the public in this great national institution, he would take steps to provide that the names of the members constituting the governing body and committees, and their proceedings, be no longer kept secret, but be published from time to time.

Mr. Grant Lawson, in reply, said the bills of quantities for the school buildings on the new site at Horsham have not, so far as the Commissioners know, yet been completed. The Commissioners are not aware that the expenditure of 20,000*l.* for draining roads, levelling and planting is now expected to be insufficient. A reduction in the number of boys has been found necessary during the period of transition through which the Hospital is passing, and it is understood that the Council of Almoners do not propose to fill the boys' school to its full extent before its removal to Horsham. The number of girls has been considerably increased since the purchase of the Horsham site in 1892. The total number of scholars is now about 200 less than in 1892. Sales of stock to the amount of about 12,070*l.* were made for meeting current expenses of the first two years (1891 and 1892) in which the scheme was in operation. Since 1892 no stock has been sold for that purpose.

The Commissioners understand that printed lists of the Governors and Council of Almoners may be purchased at the counting-house of the Hospital in Newgate Street. The Commissioners have no reason to believe that the practice of the Hospital in respect to the publication of names and proceedings differs from that of most other charities, and they have no power to make the suggested provision.

Mr. J. H. Johnstone asked whether the Commissioners had any reason to suppose that the decrease in the number of scholars at Christ's Hospital was due to the fact that the bills of quantities were in excess of the estimates, or that the expenses of laying out the grounds were more than the 20,000*l.* allowed; and whether it was not the fact that Colliers School at Horsham, which stood on similar soil, had at the present time 99 out of the 100 scholars which it was built to accommodate four years ago.

Mr. Grant Lawson said that he had no personal knowledge of Colliers School, but he had no reason to doubt that the facts stated by the hon. member were correct, and that as the bills of quantities had not yet been sent in nor the cost of laying out the grounds finally ascertained he could hardly suppose that the decrease in the number of scholars at Christ's Hospital was due to either of those considerations.

EDINBURGH ARCHITECTURAL ASSOCIATION.

DURING the winter session of this Association Mr. Thomas Gibson, of Eglinton Crescent, put at the disposal of the Council a sum of 30*l.*, to be given in prizes for the best design for a fireproof dwelling, taking as the basis of the design a house similar to those in the west end of Edinburgh. The Council appointed Mr. W. W. Robertson, of Her Majesty's Board of Works, Mr. Westland, C.E., and the then president of the Association, Dr. Rowand Anderson, to examine and decide on the relative merits of the designs submitted. In response to the invitation of the Council five sets of designs were submitted. After their examination the design submitted by Mr. James Cairns was placed first, that by Messrs. J. Gordon Smart and Louis Blanc second, and the one by Mr. Alexander Arnot third—15*l.*, 10*l.* and 5*l.* being awarded to them. Mr. Gibson, in addition to giving this money for prizes, generously defrayed the expenses incurred by the Association for printing, &c., amounting to 12*l.* The first and second successful competitors are assistant and pupils in the office of Mr. Hippolyte J. Blanc, N.S.A., and the third prizeman is of the office of Messrs. J. D. Peddie & Washington Browne.

HONOURS FOR ARTISTS.

THE effect of honours and rewards has been insisted on as a necessary incentive to artists; they ought indeed to be, they sometimes are, the result of superior powers; but accidental or partial honours cannot create genius, nor private profusion supply public neglect. No genuine work of art ever was or ever can be produced but for its own sake; if the artist do not conceive to please himself he never will finish to please the world. Can we persuade ourselves that all the treasures of the globe could suddenly produce an "Iliad" or "Paradise Lost," or the *Jupiter* of Phidias, or the *Capella Sistina*? Circumstances may assist or retard parts, but cannot make them—they are the winds that now blow out a light, now animate a spark to conflagration. Nature herself has set her barriers between age and age, between genius and genius, which no mortal overleaps; all attempts to raise to perfection at once what can only be reared by a succession of epochs must prove abortive and nugatory; the very proposals of premiums, honours and rewards to excite talent or rouse genius prove of themselves that the age is unfavourable to art, for had it the patronage of the public, how could it want them? We have now been in possession of an Academy more than a century; all the intrinsic means of forming a style alternate at our commands—professional instruction has never ceased to direct the student; premiums are distributed to rear talent and stimulate emulation, and stipends are granted to relieve the wants of genius and finish education. And what is the result? What does an Academy exhibition present in the aggregate but a gorgeous display of varied powers, condemned, if not to the beasts, at least to the dictates of fashion and vanity? What therefore can be urged against the conclusion that as far as the public is concerned the art is sinking, and threatens to sink still deeper, from the want of demand for great and significant works? Florence, Bologna, Venice, each singly taken, produced in the course of the sixteenth century alone more great historic pictures than all Britain taken together, from its earliest attempts at painting to its present efforts. What are we to conclude from this—that the soil from which Shakespeare and Milton sprang is unfit to rear the genius of poetic art—or find the cause of this seeming impotence in that general change of habits, customs, pursuits and amusements which for near a century has stamped the national character of Europe with apathy or discountenance of the genuine principles of art?

NOTES AND COMMENTS.

M. BERNIER, the architect of the Opéra Comique, which is now in course of erection in Paris, has had a model of the building prepared which is on the unusual scale of one-fourth full size. It was prepared mainly with the desire to anticipate the effects of the proposed decorations. The principal artists who have obtained commissions have accordingly co-operated in the completion of the model. When photographs are taken they will appear to be derived from the actual building. The painters will be able with more confidence to produce their large decorations, as they can realise the effect of the portions into which the pictures will be divided for the sake of convenience. The illumination of the theatre will also be facilitated by so large a model, and the effect of the electric light on every gilded ornament or moulding can be anticipated. It is remarkable to have so large a model, but if the sculptors insist on full-size figures, no matter how large may be the scale, and even if they are intended only for the adornment of a steel bridge, surely painters may be excused if they decline to risk their reputation on miniature models. No less interesting are the models of the two palaces of art which are to be erected in the Champs Elysées as part of the buildings of the International Exhibition of 1900. They are now in preparation. The scale is far smaller than is required for the new opéra-house, but they are signs of the eagerness of the modern Paris to supplement geometrical drawings by substantial models when the buildings are of sufficient importance.

THE most interesting part of the Palais de l'Industrie, which is now almost demolished, is the central portion. It has been suggested that the block should be spared the fate of the rest of the group, or if removed should be set up again as a gateway in some other quarter of Paris. That it will be temporarily preserved there is little doubt, for it is proposed to utilise it as the façade of the offices in which the numerous architects and draughtsmen who are employed on the drawings of the Exhibition buildings can labour in comfort. When the new palace is nearly complete the remnant of its predecessor can be removed. Adjoining the palace is, or rather was, the pavilion of Paris which was used for exhibitions in which the citizens were most interested. It was crammed with paintings and statues which had been purchased from time to time by the Municipality. The paintings alone numbered 984. They have been all removed to the dépôt at Auteuil, which is already overcrowded with works of art.

THE American "National Sculpture Society" now offers prizes for a design for a sundial through the generosity of Mr. T. KELLY, of New York. The prizes are 500 dols. for the best design and 250 dols. for the second best, the competition to be open to sculptors only. The sundial is to be placed out of doors on a lawn free from buildings or other objects, and no restrictions are made as to cost, the prizes being for the models alone. The designs

shall be submitted in plaster models, uncoloured, executed to a scale of 3 inches to the foot. All models must be delivered free of expense to the Society and at the owner's risk, addressed to the Secretary of the National Sculpture Society, 215 West 57th Street, New York, any time during the months of January and February 1898. The models shall bear no signature or other mark by which they may be identified, but each shall be accompanied with a plain white unmarked envelope containing the designer's name and address. Designs will be numbered in order of receipt. The competition will be judged by a committee to be appointed by the Council of the Society for that purpose, but the right is maintained to withhold the prizes in case no sufficiently meritorious design be submitted. It is stipulated that the prize designs shall become the property of Mr. KELLY, who will in no case have either of them reproduced, save by the sculptor designing it; and Mr. KELLY further agrees to place the prize designs at the service of the artists for reproduction for others than himself if it is desired. At the conclusion of the exhibition the models not receiving prizes are returnable to their owners at their expense. The Society can assume no responsibility for them after the close of the exhibition.

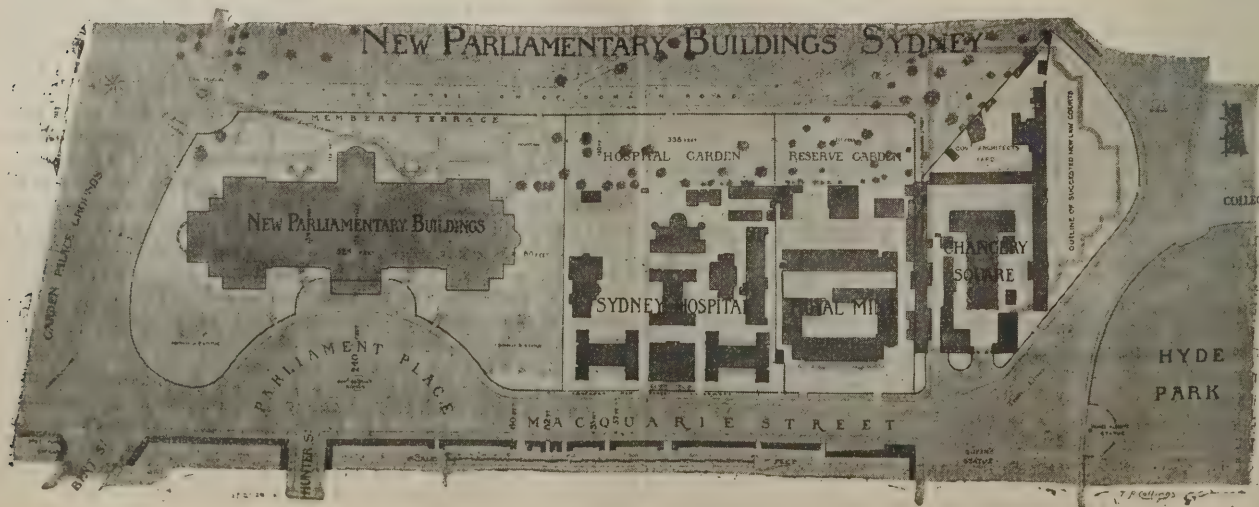

THERE is one passage in the annual statement of the Chairman of the London County Council which will gain general approval. After referring to a conference with the representatives of various bodies interested in the preservation of buildings of historic and architectural interest, of which London had so many, but of whose existence they sometimes heard only at the moment at which their destruction was threatened, Dr. COLLINS adds:—"If by preparing a register of such buildings or otherwise the Council could assist in checking such needless vandalism, it would be acting in a worthy and civic spirit." Much will depend on the meaning which the word "otherwise" is to have, for although a register of the old buildings of the Metropolis would be most useful, yet we need not invoke the machinery of the Council for so simple a matter. Will the Council do whatever is necessary at a reasonable expense to preserve the buildings from destruction? In that way some of the errors of the Council would be condoned. What is no less important, the example would be likely to find imitation in other councils.

THE SOCIETY OF ARTS' EXAMINATIONS.

THE Society's examinations are conducted simultaneously at a number of different centres throughout the kingdom, through the agency of local examination committees established for the purpose by the Society. The papers in each subject are sent down in separate envelopes to the secretary of the committee immediately preceding the day of examination. The envelopes are opened in the presence of the candidates, and the papers distributed. The worked papers are sealed up at once and despatched to the office of the Society. In the present year, 1897, 7,513 papers were worked by 6,919 candidates at 221 centres. The subjects in which examinations are now held are:—1. Arithmetic; 2. English; 3. Book-keeping; 4. Commercial Geography; 5. Shorthand; 6. Type-writing; 7. Economics; 8. Précis-writing; 9. French; 10. Elementary French; 11. German; 12. Elementary German; 13. Italian; 14. Spanish; 15. Elementary Spanish; 16. Portuguese; 17. Russian; 18. Danish; 19. Chinese; 20. Japanese; 21. Domestic Economy; 22. Rudiments of Music; 23. Harmony; 24. Practice of Music.

The examination system of the Society of Arts was an outcome of the Great Exhibition of 1851, which, as is well known, was originated by the Society.

In November 1851, Mr. Harry Chester, then a vice-president of the Society, and afterwards chairman of the Council, submitted to the Council a scheme for the formation of a union of mechanics' institutions, the principal object of which was to encourage the founding of such institutions, and to develop the educational facilities which they provided.

Among the early suggestions for the utilisation and development of such institutions was a proposal for a general system of examinations among their members. In December 1853 Mr. Chester definitely proposed the establishment of such a system, and in the spring of 1854 a scheme of examinations was published. The scheme was of a very comprehensive character, and included the following subjects:—1. Mathematical Sciences; 2. Experimental Sciences; 3. Sciences of Observation; 4. Mechanical Sciences; 5. Social Sciences; 6. Fine Arts; 7. Moral and Metaphysical Sciences; 8. Literature. This very elaborate programme proved a little impracticable, and it is not to be wondered at that only a single candidate offered himself for examination in March 1854. The promoters of the movement were not, however, discouraged; the scheme was remodelled principally by Dr. Booth, at that time an active member of the Society, and in 1856 an examination of fifty-two candidates was held at the Society's house. The subjects of the first examination were:—1. Book-keeping; 2. Arithmetic; 3. Algebra; 4. Mensuration; 5. Geometry; 6. Mechanics; 7. Chemistry; 8. Animal Physiology; 9. Botany; 10. Agriculture; 11. Geography; 12. Physical Geography; 13. English History; 14. English Literature; 15. Latin and Roman History; 16. French; 17. German; 18. Freehand Drawing.

In the following year, 1857, the first attempt at provincial examinations was made, and an examination was held at Huddersfield, as well as in London, the examiners of the Society going down for the purpose. The desire of increasing the number of examination centres and the obvious impossibility of sending examiners simultaneously all over the country led in 1858 to the elaboration of the system of local committees to supervise examinations worked from a single centre.

The Society of Arts, however, cannot claim the sole credit of the invention of the system of local examinations. In 1850 the College of Preceptors (established in 1846) was considering the best means of examining the schools of its members. It commenced by sending down examiners, but in 1853 the experiment was tried of collecting pupils to a centre and examining them by means of papers sent down from London. The experiment proving successful, the system was regularly organised in the following year, 1854, and has been continued ever since.

It will be seen that the College of Preceptors' examinations preceded those of the Society of Arts by two years, but the objects, the conditions and the methods of the two systems have been so different that there has never been any but the most friendly rivalry between them. In 1856 a conference was held at the Society's house between representatives of the two bodies, the College being rather afraid that the Society's examinations would interfere with their own. It was soon apparent that the two systems were intended to occupy different ground, and were not likely to affect one another. In practice this has proved to be the result, and it has never been found that the two systems have interfered in the least with one another.†

To the Society's examinations in 1858, 58 institutions sent up 288 candidates; in the following year there were 480; in 1860, 586. The numbers increased steadily till 1865, when

there were 1,899; the next year showed a slight diminution, and then there was a further increase, till the number of 2,160 was reached in 1869.

The University Local Examinations were established in 1858. The establishment of elementary drawing examinations by the Department of Science and Art was about contemporaneous with that of the Society's examinations. The science examinations began later, in 1861, and as these developed, it was found that the Society's examinations were in many respects competing with those of the Department. The same candidates were being examined in the same subjects, and there was an evident waste of power. In 1870 this led to the abandonment of seventeen out of the thirty-six subjects then included.

In 1871, when the Council were considering the establishment of a system of technological examinations, of which an account is given below, they passed a resolution to discontinue the general examinations, but on the application of some of the more important institutions in union, they rescinded the examinations resolution and determined to continue for a further period. This was done on the same system as before, till 1876, when the programme was revised, and the plan on which certificates were granted was somewhat modified. Previously, certificates had been granted for single subjects, but in that year a "Commercial Certificate" was established in addition, to take which it was necessary to pass in, at least, three subjects. Very few of these certificates were ever taken, the system of single certificates for single subjects being more popular and better suited to the needs of the class of students who take up the Society's examinations.

In 1879 the question of abandoning the examinations again arose, it being thought that the ground was covered by other agencies. To quote from the report of the examination committee in 1879:—

"The committee feel that the time has now come when the Society should cease to compete with other educational agencies more influential in the work of examination. With the Educational Department examining millions of children in elementary schools and thousands of young persons in night classes; with the universities holding their local examinations throughout the country for young persons of a higher class; with the Science and Art Department examining students in every branch of science and art; with the new City Institute developing yet further the technological examinations just handed over to them by the Society; with other agencies, such as the College of Preceptors, doing kindred work, the Society of Arts may well retire from the field, having in all these various directions acted as the pioneer. It held science examinations before the Science Department, examinations in literature before the universities went afield to meet the classes who could not go to Oxford or to Cambridge. It has seen the system it established develop, with the aid of Government funds, as it could never have grown without such help, and the time has now arrived when it may cease to compete with the agencies it has done so much to foster."

In pursuance of the course mentioned in this report, no examination was held in 1881, but again, however, some of the institutions where the examinations were held protested, and on further consideration it was determined to continue the examinations, but to try whether they could not be made self-supporting. Hitherto they had been free. In 1882 a fee of 2s. 6d. was charged to each candidate, and this charge has been continued to the present date. The "Commercial Certificate" was abandoned, and the old system was resumed of giving a separate certificate for each subject. The natural result was a considerable falling off in the numbers examined. In 1882 only 695 papers were worked as compared with 2,325 in 1880. The numbers, however, soon began to increase again. In 1890 there were 2,474; in 1894, 4,375; in 1895, 5,108, and in the present year, 7,513. This very considerable increase is doubtless, to a very great extent, due to the fact that the county councils have now large funds available for the promotion of technical education; and that certain commercial subjects are scheduled by the Science and Art Department as subjects coming within the scope of the Technical Instruction Act, 1889. The commercial subjects so scheduled are precisely those in which the Society of Arts has now for just forty years been holding examinations.

The technological examinations, referred to above, were instituted in 1873 at the suggestion of Sir John Donnelly. These examinations were intended to test the knowledge possessed by artisans of the subject-matter of their respective industries. It was arranged that they should be held in connection with the May examinations of the Science and Art Department, the technological papers being given out with those of the Department. Before a candidate could obtain a certificate he was required to pass a Department examination in certain specified science subjects, these varying according to the technological subject taken up. Certificates of three grades were given—elementary, advanced and honours—corresponding with those of the Department examiners. No attempt was

* A paper by Sir Henry Trueman Wood, M.A., secretary of the Society, read at the International Congress on Technical Education.

† The writer of this memorandum may be permitted to mention that he was for a short time one of the examiners of the College.

made to test practical skill, but each candidate was required to produce a certificate from his employer in which his competence was stated. The number of candidates was never great. In the first year (1873) only six entered, and the numbers gradually increased to 68 in 1870 and 184 in 1878.*

In 1879, on the foundation of the City Guilds Technical Institute, the technological examinations were handed over to that body. From the funds placed at its disposal by the City companies the Institute was able to offer to teachers payments on the results of the examination in the same manner as the Science and Art Department does for its examinations. Teachers were thus enabled to form classes and send pupils for the examination, and a large increase in the number of candidates took place. These examinations now form an important part of the Institute's work and attract annually a very large number of candidates. In 1897 the number entering was 29,494. Large additions have also been made to the list of subjects, which now number sixty-three. No great change has been made in the general character or system, which remains much the same as that proposed by Sir John Donnelly, but the details have been considerably modified and in some cases a practical examination to test handicraft skill has been provided.

In addition to the examinations above referred to, the Society conducted, from 1856 to 1894, elementary examinations. These were really carried on by district unions and local boards in connection with the Society. All the Society did was to supply identical examination papers, the results being examined and certificates awarded by examiners appointed by the local boards. The Society supplied the certificates, but accepted no responsibility as to their award. The system, though useful at its first establishment, was never found to work in a very satisfactory manner, and in 1895, the place of these examinations being better filled by examinations entirely under the control of local institutions, the Society's system was abandoned.

THE ROMAN COUNTRY HOUSE.†

IN all the detailed enumeration by Pliny of the charms of his two favourite villas—the winter villa at Laurens and the villa at Tuscum, where he preferred to pass his summer leisure—what is not said is almost as remarkable and suggestive as what is said. There is a general impression of amplitude and luxury, indeed, of magnificence in the descriptions, but hardly a word is vouchsafed regarding the architectural dress and detail of this extensive abode. We have no hint of precious marble wainscoting, of panelled and gilded ceilings of cedar, of Grecian mosaic and columns of porphyry. It would seem that splendours of this kind were to Pliny's mind beneath the notice of a literary man and philosopher, betraying conceit or vanity if paraded in his own letters—as if one should exalt the elegance of his own dress, or that he had really preferred to expend his ample resources upon size and comfort, extensive grounds and delightful vistas, rather than upon ornament and display. He might have said with Horace:—

No ivory, nor gleam of gold
From panelled ceiling richly carved and fair
Within my home mayst thou behold,
Nor beams Hymettian, upborne on rare
Numidian shafts from Africa's shore, &c.

Yet we know that the period of Trajan, to which these villas belong, was one of great splendour of material in architectural work, and especially in the use of costly marble from distant lands.

Another peculiarity of Roman dwellings generally was the moderate size of the rooms in the more private and domestic portions of the residence. The bedrooms, for instance, were for the most part of small dimensions. This is true even in the great Villa Hadriana, at Tivoli, in spite of its extraordinary magnificence. Pliny mentions the loftiness, but not the spaciousness, of any of those in his own villas. On the other hand, the *triclinia* and banquet-halls were often of considerable size. But the extent of the larger villas is remarkable rather in respect to the number than the size of the several rooms. Suite after suite is mentioned. Private apartments, libraries, drawing-rooms, porticoes, sitting-rooms and galleries succeed each other again and again—each with a different exposure, view, or degree of seclusion. What is the explanation of this extravagance of reduplicated accommodation? The answer is threefold. In the first place, these arrangements reveal a certain restiveness within walls. If compelled to remain in his residence, the Roman must at least have constant change of scene provided.

To spend a whole day shut into two or three rooms would have been imprisonment to him. Accustomed in the city to long vistas, imposing perspectives and endless colonnades, he refused to be more closely confined in inclement weather in his villa than in town. Hence the long suites of porticoes, porches, galleries, drawing-rooms with endless windows and doors, closed by shutters or portières, or in some cases with glass. Even in his villa the Roman could feel distance, space and change, and stroll up and down the long halls with his friends. For the same reason the architectural effects were chiefly those of long perspectives and multiplied openings, not the magnificence of carving and precious incrustations. These were reserved for the *thermae* and dining or banquet-halls, where hours together were passed at a time. The walls of all rooms were painted more or less elegantly after the manner we call Pompeian, and the floors set with *opus tessellatum* or *Grecanicum*; but there was much less effort at sumptuousness in interior decoration in the living rooms than we are apt to imagine.

The second reason for the vast size of the villas is to be found in the Roman habits of hospitality. The wealthy Roman was expected to entertain hosts of guests. These required a great number of apartments, and Pliny tells Gallus that at Laurens "most of the apartments in this side of the house appropriated to his slaves and freedmen are sufficiently elegant to entertain any of my friends who are inclined to be my guests." Statesmanship and public life had their drawbacks then as now, and the wealthy and influential Roman of Pliny's time was compelled by his rank and condition to entertain hosts and hordes of friends, admirers, clients and sycophants, who were liable to descend upon him at any time. In one letter Pliny begs a friend to forewarn him of his coming that he may have the baths heated and ready in good season against his coming. The sudden and unexpected invasions of friends and politicians must be provided for; hence this seemingly extravagant multiplicity and reduplication of rooms.

In the third place, one must bear in mind the slave system of ancient Rome, which rendered wholly unnecessary many of the economies of disposition practised in modern housebuilding, even among the wealthy. An army of dependents was at hand to wait upon every wish of the master, making not only possible but necessary a spreading out of the apartments and a multiplication of accommodation almost incomprehensible to our minds.*

If from generalities we proceed to details, the path is not so clear before us, at least with regard to the dwelling. To restore a Roman country residence with anything like confidence in the correctness of our results is not possible. Everything we have but the details; these are singularly lacking. Even the general plan of the villa dwelling can only be conjectured. While we have ruins of almost every other type of Roman building sufficient for a fairly complete restoration of at least the plan, of not one villa-dwelling can the ground plan be traced with adequate completeness. We are thoroughly acquainted with such house-types as those of Pompeii and Herculaneum, and with other examples of the urban and suburban dwelling in Rome and the provinces. On the Palatine Hill, at Spalato and in the ruins of Tibur (Tivoli), the imperial ages have bequeathed to us important and splendid remains of the magnificent palaces of the rulers of the antique world. But on the sites of the ancient villas all remains of the houses themselves seem to have vanished, although the terraces and gardens, *piscinae* and colonnades have in many cases been admirably preserved, as at Castel Gandolfo, where the modern villa in its landscape gardening follows absolutely the lines of the Villa of Domitian. For our conceptions of the dwelling, therefore, we are dependent largely upon literary sources, and the two letters of Pliny already cited, with others in which briefer reference is made to his estates, and incidental passages in Cicero, Varro, Vitruvius and other writers, must be the basis of all our restorations.

The restoration both of the Laurentian and Tuscan villas has been a favourite problem with archaeological architects. I have before me plans of the former by Bouchet, Semper and two former students of the Massachusetts Institute of Technology, and of the latter by Semper. The very great variation between the different versions of the Laurentian house reveals the difficulty of working from a familiar description instead of a detailed specification. It soon becomes evident that Pliny has omitted to mention many of the rooms and accessories of the plan, while the precise relation between the different parts is not always easy to conjecture. Who nowadays would expect to be able to draw a correct and detailed plan of a large American or English country house from a mere epistolary description in the familiar correspondence of its owner? The

* The following were the subjects included in the 1878 examinations:—Cotton manufacture, paper, silk, steel, carriage-building, manufacture of pottery and porcelain, gas manufacture, glass, cloth, silk-dyeing, wool-dyeing, calico-bleaching, dyeing and printing, alkali manufacture, blow-pipe analysis.

† From a paper by Mr. A. D. F. Hamlin, in the *Architectural Review*.

* The slave population of Rome in Pliny's time is believed to have outnumbered the free by a ratio of three to one, and it was not uncommon for a well-to-do citizen to own as many as 500 slaves or more. Upon a single estate, like that at Laurens, there would be at least 100, of whom the half were most probably lodged in the villa itself. This estimate may very possibly be much too low.

wonder rather is that agreement should prevail as far as it does in the efforts of different persons to reconstitute the plan of the house so charmingly but unscientifically described by the distinguished Roman advocate.

One important question not fully solved is that relating to the number of storeys. It is commonly assumed that Roman houses, other than the great tenement-house blocks or *insulae*, were but one storey high. This assumption is probably correct in the main and is supported by many considerations, but I cannot think it is demonstrated for the villas. The Pompeian and Herculanean ruins for the most part show houses of one storey, except where, as in the so-called Villa of Diomed, outside the walls of Pompeii, the slope of the site naturally dictated for a part of the plan a second storey. Only in one or two cases are stone stairways to be found or any demonstrable provision for wooden flights. The references to stairs or to upper storeys in the letters to Pliny and Cicero, in Vitruvius and Varro, are singularly scanty, and the broad extent of the plans described by these writers certainly points to a strong preference for living on one floor, and that on the ground level. Moreover, the great care taken to exclude dampness by hypocausts, and the importance of the *atria*, peristyles and courts in the domestic life of the Romans, prove that rooms on an upper floor could have been little used by the family, either as living, sleeping or sitting-rooms. Without doubt the life of the inmates, the owners of the villas and their guests, was almost wholly passed on the ground floor.

Yet the few exceptions noted in Pompeii and the specific description by Pliny of two second-floor apartments of several rooms each at Laurens, prove that upper rooms were not unknown and that they were not in all cases, at least, assigned exclusively to slaves and attendants. The advantages of elevation, both for the sake of a wider prospect and of the freer movement of the air, would render desirable the provision of at least a limited number of upper chambers. These would have the further advantage of completer privacy, a deeper silence and greater remoteness from the movement and chatter of the throngs of clients, serfs and guests in the *atrium*, *cavadium* and more public parts of the villa than could be had below. They may have been confined to the remoter parts of the villa, except where, as in the house at Laurens, they formed one or more square turrets, dominating the general mass (as shown in Bouchet's perspective) and breaking its long horizontal roof-lines. No one denies that on sloping sites, as at Tuscum, the second storey became indispensable. But in this case it was reached from the upper level and only incidentally served by interior stairs, perhaps of wood. The grand staircases of modern palaces were wholly unknown in Roman interiors.

The external mass and composition of the villas, like the plans, was irregular and picturesque. We know almost nothing of their decoration, or whether they were at all treated with any special external elegance. The Italian villas of the sixteenth century, like the Pia of the Vatican, the Medici, the Pamfili Doria, with their three or four storeys, their graceful turrets, open loggias and playful richness of adornment, can hardly claim any resemblance to the Roman dwellings, however closely their gardens follow the antique models.

The literary documents are, as we have said, curiously brief or silent with reference to the interior decoration of the villas. Pliny and Cicero have little or nothing to say about wall-paintings, floor-mosaics, columns or marble incrustations. The treatment of ceilings is not mentioned. But precisely where the books are silent the architectural documents supply the lack. The villas themselves—that is, the houses—have wholly perished. But however widely these may have differed from city dwellings and suburban residences in arrangement and general aspect, the detailed treatment of floors, walls and ceilings must have been in substantially the style exhibited by the ruins of the larger and finer houses and palaces of the cities.

For the most part it would appear that the walls built of rubble or concrete, faced in some cases with brick, were finished both externally and internally with stucco and a fine smooth coating of plaster to receive painted decorations. The painting was, for the more ordinary work, of the kind called *tempera*, in which the medium was water thickened with gum or glue. But the finer paintings were executed in encaustic colours. For these wax was the medium; the colours were applied warm with a sort of spatula, and graded, scumbled and spread with the help of hot irons held near the wall to soften the fast-hardening wax. The result in skilful hands was a remarkable combination of vigour and finish. The style of decoration used was that made familiar to the modern world by the ruins of Pompeii and commonly called Pompeian. The name is a misnomer except when carefully restricted to the local peculiarities observable in that city; the general style prevailed throughout the Roman world. The finest examples indeed of this style of wall-painting are to be seen in Rome. Upon the Palatine those extraordinary subterranean ruins known as the *Thermae* of Titus, in which the substructions of Titus's Baths and of the Golden House of Nero are so strangely mixed, offer many beautiful examples of the art. It was from these that

Raphael learned the style of fresco decoration which he, with Giovanni da Udine and Giulio Romano put to such masterly use in the Vatican *loggie* and elsewhere. The Casa Livia, on the Palatine, presents other examples of the art, while in the Museo delle Terme are several walls removed bodily thither from a house exhumed on the banks of the Tiber in 1879, in which the painting of light and fanciful architectural ornaments, wreaths and festoons, on a ground of black or dark red, has been carried to a degree of refinement and elegance hardly matched in any other example.

Besides this so-called Pompeian painting, with its fantastic architecture in impossible perspective, its wreaths and garlands, and its graceful figures floating airily on the rich dark background, the walls of Roman villas received other decorations, such as wainscoting with marble or draping with hangings and tapestries from Eastern looms. Marble veneering, which the Romans used with such lavish hand in their *thermae* and basilicas, was wholly confined to the imperial period, for in 88 B.C. M. Lepidus was censured for providing his house with a threshold of Numidian marble. But the use of marble once introduced became a fashion, then a fad, finally a craze. We may be certain that in the later villas the flash and sheen of polished marble from Numidia, from the Sea of Marmora, from all parts of Italy was everywhere present. Where and when marble was beyond the means of the owner an imitation of its veinings, colours and surface often took its place, executed in hard plaster. Roman taste was never fastidious on such points—not more so than the modern taste which tolerates galvanised-iron cornices, shamming stone, or lath-and-plaster Gothic vaults.

Besides these resources of colour the Roman mural decorator made most effective use of modelling in low relief in the wet plaster. Most of the work of this sort that has come down to us shows an extremely delicate and artistic treatment of the relief. It appears to have been wrought freehand, for the most part if not entirely, and, as the drying of the plaster necessitated rapid work, it has a peculiar charm, a snap, a freedom and individuality which render it extremely attractive and well worthy of study. It is a style of work which might easily and wisely be revived in this time and country, for it can be made as monumental or as playful as may be desired, and is admirable as an adjunct to mural paintings.

Ceilings were probably of wood or plaster, except in corridors, crypto-porticoes, baths and a few of the monumental apartments in which vaulting was employed. No vestiges or moulds of panelled wooden ceilings have been preserved to us in the ashes of Pompeii or the ruins of villas or palaces. The concrete-and-brick coffering of the Pantheon and Basilica of Constantine, and the richer panelling of some of the stone ceilings of Palmyra and Baalbec, give us suggestions of the probable treatment of the more important horizontal ceilings, while those of the minor rooms were in all likelihood plain flat plaster ceilings, more or less enriched with painting.

The furniture of the villa was in keeping with its extent and cost. Some of the accounts we have of Roman extravagance in this respect are almost incredible. The luxury there displayed was, however, of a somewhat different character from that of modern times. It was more ostentatious, but far less comfortable. Silver, gold and bronze, marble and ivory were the materials most favoured for the long couches or beds of the *triclinia* (dining-rooms) and the thrones and tables of the rooms of state.

The furniture was sumptuous, ponderous, often admirably designed, but stiff, formal and cold according to our notions. It is of course possible that wood and upholstery, to which we owe the luxurious ease and comfort of modern furniture, were more largely used than the paintings and reliefs would indicate. But whatever may have been lacking in this respect was more than made up by the splendour of the surroundings; the Oriental rugs and tapestries, the perfumed silken *velaria* or awnings intercepting the hot sun's rays, the babbling fountains in basins of silver, mosaic or marble, the magnificent floors of mosaic, the brilliant colours of the court walls, the flash and glitter of silver and gold, the vistas through colonnades, halls and courts; while attentive servitors waited upon every want of the owner and his guests, and music, poetry and the luxury of the many-chambered bath served to add physical and intellectual pleasures to the delights of the eye.

Doubtless there were discomforts. Glass was costly and rare as a filling for windows—it was neither smooth nor clear. Horn and mica and oiled parchment would seem to us poor substitutes for plate-glass, and dripping and odorous and smoky oil lamps, however graceful and artistic in form, a very inadequate and trying means of illumination at night. With all the ingenuity of the varied exposures of the Roman villas, the wind and cold could not well be shut out without also shutting out the sunshine and daylight. The modern fiction that sunny south lands are always warm did not keep the ancient Roman from shivering in December or March, any more than it does the modern tourist in Italy. The hypocausts and furnaces of the antique villa, at the cost of an enormous con-

sumption of fuel, could hardly in severe windy weather have warmed Pliny at Laurens as comfortably as a modern hot air or hot-water furnace in the 5,000-dollar house of an American village shopkeeper.

The conditions which produced the Roman villa can never exist again. But the landscape gardening and the architectural embellishments which surrounded it had much in them which it has proved possible to revive in modern times, and are full of lessons for those worthy persons of artistic tastes who are minded, in our day, to surround themselves with whatever is sumptuous and beautiful in nature modified by human art.

THE EASEMENT OF SUPPORT.

THE following judgment was delivered on Monday in the Court of Appeal by Lord Justice Lindley in *Howarth v. Armstrong* :—

The plaintiffs and the defendant are respectively entitled, as lessees under the Ecclesiastical Commissioners, to two adjoining houses in Drake Street, Rochdale, and the question raised by the appeal is whether the defendant is entitled to have his house supported by one of the walls of the plaintiffs' house. The Vice-Chancellor has decided that the defendant is so entitled. The plaintiffs contend that he is not. The question arises in this way. In 1797 both houses belonged to the vicar of Rochdale, and he granted one long lease, ending in 1895, of them both. Each house was afterwards sublet separately from the other, and in 1864 each was held under a sub-lease which expired a few days before the head lease. Up to this time (1864) neither house supported any part of the other. Each had a garden in front, and between the two gardens there was a low wall 11 feet 3 inches long, in a line with the south wall of the plaintiffs' house. In 1864 James Howarth was sub-lessee of the plaintiffs' house, and James Chadwick was sub-lessee of the defendant's house. Howarth had raised the above-mentioned 11 feet 3 inch garden wall to the extent of about 13 feet, with the permission of Chadwick. By an agreement dated October 3, 1864, Chadwick agreed to let Howarth maintain the wall so built by him during the remainder of the head lease of 1797, less the last twenty days thereof. For this permission Howarth was to pay 5s. a year. This agreement treats the low garden wall on which Howarth had built as Chadwick's wall. In 1870 the sub-lease of the defendant's house was vested in Armstrong by assignment from Chadwick. Armstrong had, with Howarth's permission, built into his wall, and by an agreement, dated March 25, 1870, Howarth agreed that Armstrong might maintain and enjoy Howarth's wall during the remainder of the head lease of 1797, less the last twenty days thereof. For this permission Armstrong was to pay 5s. a year. This agreement is not clear as to what wall of Howarth's was meant. I understand, however, that it included not only that part of the south wall of Howarth's house which has been called his gable wall, but also the wall which Howarth had erected, with Chadwick's permission, on the 11 feet 3 inch garden wall already mentioned. At any rate, as I understand the facts, Chadwick did put beams into this raised wall with Howarth's consent, as stated in the agreement of 1870. The material fact to be borne in mind is that, whatever cross-easements were agreed to be granted by one lessee to the other in 1864 and 1870 as before mentioned, those easements were temporary only, and were created by agreements to which the lessors were not parties, and those agreements came to an end in 1895, twenty days before the expiration of the head lease of 1797 and ten days before the expiration of the sub-leases under which the tenants held their respective houses. Pausing here to consider what the rights of the tenants would have been when the agreements of 1864 and 1870 came to an end if nothing further had happened, it seems plain that each could have removed or required the removal of what had been built into his own wall. This right would have come to an end in the sense that it could not be infringed after the expiration of the sub-lease under which he himself held. Still, the existence, even for a short time, of this right of removal becomes very important in considering the effect of what took place in 1871. In that year Howarth, without surrendering his underlease, obtained a new lease from the Ecclesiastical Commissioners for a term of 999 years, to be reckoned from the date of the lease, *i.e.* 1871, but as regards possession to take effect from one day after the expiration of the subsisting head lease of 1797, *i.e.* 1895. In March 1889 Armstrong also obtained a long lease of his house from the Ecclesiastical Commissioners framed in the same way. There is nothing to show whether the Ecclesiastical Commissioners had or had not any knowledge of the agreements come to between the tenants of the two houses in 1864 and 1870 as above mentioned. The Vice-Chancellor has decided, and it is now admitted, that the plaintiffs' lease of 1871 comprised the whole of the walls referred to in the agreements of 1864 and 1870, and since 1895, when the head lease

of 1797 fell in and those agreements came to an end, those walls, including the 11 feet 3 inches garden wall (treated in 1864 as Chadwick's), and the erection upon it, have been the plaintiffs' for the rest of their present lease. The question is whether the defendant has acquired any right to keep the ends of his beams in the plaintiffs' wall, although the agreement under which his predecessor put them there is at an end. There is no agreement between the plaintiffs and the defendant conferring any such a right on the defendant. But he contends that the lease by the Ecclesiastical Commissioners of the plaintiffs' house to the plaintiffs in 1871 operated so as impliedly to reserve to the lessors a right to have the defendant's shop supported as in fact it then was, and that this right passed to the defendant by his lease of 1889. This view has been adopted by the Vice-Chancellor, and its correctness turns on the terms of the lease of 1871. An examination of this lease shows that the lessors reserved the mines and minerals under the property demised, but nothing else in express terms. The covenants by the lessee are, however, very important. Howarth agreed with the Ecclesiastical Commissioners that he would keep up the value of the property demised to an amount there specified by maintaining and repairing the then existing house, or by rebuilding or improving it, or by erecting one or more other houses in lieu of it or in addition to it. The appellants counsel contended that this was inconsistent with any implied reservation of a right to have Armstrong's house supported by the house demised to Howarth. But the lease contains other covenants by the lessee which require attention. There is a covenant by the lessee that he will not carry on certain trades, "nor do or permit to be done anything which may tend to the annoyance or damage of the other tenants of the glebe land," by which is meant other adjoining land belonging to the Ecclesiastical Commissioners, including that which they afterwards let to Armstrong. Then there is a covenant to keep the property demised in good repair, and so to yield it up at the end of the term. The lease to Armstrong is in similar terms, and the same form of lease is no doubt adopted by the Ecclesiastical Commissioners for all their property forming what is called the glebe land. The Ecclesiastical Commissioners are not parties to this action, and it is not necessary to consider whether they could obtain an injunction to restrain the plaintiffs from removing the defendant's beams and thereby annoying and damaging him. On this point I express no opinion. But, assuming that such an action could be maintained, I have come to the conclusion that it would be going too far to hold that the lease to the plaintiffs in 1871 impliedly reserved to the lessors the right to have the adjoining house supported by the plaintiffs' wall. Such a reservation cannot, in my opinion, be treated as dating from the date of the lease of 1871, for it was not to come into operation, as regards the interest and right of possession, until 1895. As regards easements impliedly reserved to the lessor, the lease of 1871 can only be treated as coming into operation from the end of the old head lease of 1797—that is, from 1895—but it was quite uncertain in 1871 what the state of things would be when the old head lease would come to an end. Both houses might then have been restored by the tenants to the state in which they were before the agreements of 1864 and 1870 were entered into. To stipulate for a future easement of support, if wanted, might be reasonable enough, but such an easement cannot be implied on the ground of necessity, nor upon any other principle with which I am acquainted. It was contended that the lease of 1871 should be treated as if granted in 1895, and as a lease of the plaintiffs' house as it then stood. But it is, in my opinion, impossible so to treat the lease. We must take it as it is, and not as if it were something quite different. The peculiar facts of this case render the authorities relied upon by defendant inapplicable. *Roach v. Jones* is the nearest, and might have covered this case if the lease of 1871 had been granted in 1895, and if the plaintiffs' and defendant's houses had been then in the state in which they in fact were. But courts cannot legally imply reservations of easements unless it is clear that such reservations are necessary in order to give effect to the real arrangements which the parties were making, and in this case I am unable to come to the conclusion that there is any such necessity. The appeal, therefore, must be allowed, and it must be declared that the defendant has no such easement of support as he claims. This being the controversy between the parties, and the defendant being in the wrong, he must pay the costs here and below.

Lord Justice Lopes and Lord Justice Rigby concurred.

The Bill authorising the New River Company to raise 1,000,000l. additional Debenture stock has passed the House of Lords as an unopposed measure. The money raised by this issue will be spent upon providing the company with an independent line of pipes from the authorised Staines reservoirs.

"THE GRAVES" AT KILHAM.

ONE of the most important and interesting archaeological discoveries of recent years has been made at Kilham, on the East Yorkshire Wolds, when, under the auspices of the East Riding Antiquarian Society, several of the small tumuli popularly known as the Danes' Graves were opened. These mounds, of which there are 178, says the *Eastern Morning Post*, have for centuries been variously regarded by the historian as the resting place of either Danish settlers or those who fell in battle, probably against Harold. The conjecture of the historian, supported as it has been by local belief, has now, however, been proved to be entirely false, and we have it on the word of Canon Greenwell—perhaps the greatest living authority on these matters—that far from being the graves of Danes they belong to an age at least 1,000 years before the Conquest; that is, to about 2,000 years ago, and prior to the Roman invasion. To this conclusion he has come after an exhaustive examination of the tumuli, of which thirteen were laid bare, and in one of which were found not only the bones of the ancient Briton quietly reposing there, but the iron tyre of his chariot, the iron bit and trappings of his horse, and, most interesting of all, a bronze pin, beautifully designed and enamelled. The discovery of these, together with the shape of the graves and the curled-up position of the skeletons, leave no doubt as to the age to which they belong, and satisfactorily dispose of the wrong theory which has prevailed for generations.

For some days past the excavations have been going on under the careful guidance of Mr. J. R. Mortimer and Mr. Thomas Boynton, permission having been given by Mr. Harrison Broadley, who, we understand, has expressed the wish that whatever may be found shall be deposited in the York Museum. When, therefore, the visit was made by a number of members of the East Riding Society, the work was in an advanced state, and they were rewarded by the sight of the valuable finds to which we have already briefly alluded.

Canon Greenwell prefaced his remarks with a brief sketch of the races which have occupied the land from the earliest times. Beginning at the beginning, he said that of the earliest occupants of England they had no trace whatever in this part of the country. He did not think that there was any trace of them whatever further north than the south of Norfolk, and when he had to speak of these earliest inhabitants and some later ones down to the people who threw up those mounds, he would not speak dogmatically, but rather tentatively, because they really knew very little on the subject. The first people in England was Palæolithic man, who used stone implements. They had found no bony remains which could be attributed to him. There had been several skulls attributed to that time, but he thought that there was no evidence to show that they did not belong to a later period. Therefore, they had not to regard these early people from their bony constituents and personal appearance, but from their stone implements and so forth found in the gravel beds of rivers. These implements found in these river gravels were never ground or polished. They were all no doubt acquainted with polished stone axes found in the land, these were reduced into form undoubtedly by chipping, and there was no instance known where implements of that period had been found which showed the least trace of grinding or polishing. It was quite vain to say—quite foolish to say—what they were intended for, because they did not bear sufficient indication to enable them to be described as a spear-head, a knife, and so on. Having described other features of the Palæolithic age, Canon Greenwell said that it was impossible to fix anything like an approximate date for it. Some had said 200,000 years, some a million, some 20,000; at any rate, they might be quite certain that a very, very long time had elapsed. They had records in Egypt going back 4,000 or 5,000 years before Christ, and they had representations of animals and fauna of that country in abundance. There was no difference between them and the present; but in the Palæolithic age they had man associated with implements of a different class, and changes in the animal life and fauna which could only take place after a very long period. Up to the present day they had not been able to bridge over the distance between the Palæolithic and Neolithic age—the time when implements were ground and polished. There was no trace of the bridging. It must be that man was driven out by the glacial descent to a more southern place. Some day we might get all the evidence. Up to the present we had made mere scratchings on the earth's surface; a great part of the globe was practically virgin soil in that respect. These Palæolithic implements were spread over a very wide area—France, Spain, Syria and Egypt. One of the most extraordinary discoveries had been made in Somaliland, where implements had been found in large numbers. He had no doubt that what had been found in that spot would be found all over that country. Those which had been found were precisely identical with everything in this country, and it was quite difficult to think that they could have been made without some intercourse and copying. With regard to the Neolithic age—a very much later period—he could not tell them anything at all positively. The skulls of these people

were of the long-headed type. We could find the most typical Bronze period headed men and Stone headed men living amongst us to-day. The Neolithic people buried in a peculiar form of mound—a long one—and we found very few articles buried with them; and we did not find many implements, but some pottery which was quite different from the pottery of the Bronze period. In the Bronze period we came to a time nearer our own, but he did not think it would be safe to say with any certainty when the Bronze people arrived in this country. He had no doubt that they were an invading people who conquered the long-headed people, and were not so tall, not so strongly made; they were pleasanter-looking people, because the bony remains showed that they were really a very good-looking people indeed, with soft features and without the high cheekbones of the Bronze people. The Bronze people came into the country across the sea. The South Germans approached more than any others in their appearance to these round-headed people. He thought that the bronze-using people came with superior material, being a stronger people, and that they conquered the stone-using people. Some might think that they extirpated them, but it was very rarely that the conquerors extirpated the old inhabitants in days gone by, when all the people were white people with the same mental characteristics, and more or less people descended from the same general stock, and therefore did not absorb each other. The primary interments in the long barrow were always round-headed people, but when one came to the barrows of the bronze-using people, there were round and long-headed people, and a mixture of the two. Seeing that when the round-headed people invaded the country they did not extirpate the other, but lived with them and intermarried with them, these people were the persons who raised all the enormous quantity of barrows which remained over the Yorkshire wolds and other parts of England, and due to the examination of these sepulchral mounds we had obtained a great deal of information about the people, their mode of living, and, to some extent, of their political constitution. It was fallacious to suppose that these people went about without clothing and painted their bodies. On the contrary, they were clothed nearly as well as we were. Buttons and various classes of dress had been found, so we must put out of our heads altogether the notion that the Bronze people were savages. They were people possessed of a considerable amount of civilisation, and had beautiful weapons and implements, because nothing could exceed the grace of the spear-heads and swords used by them. After the Bronze period we come to what was the early Iron period, or late Celtic period, and in this the proceedings of that day were centred. He was standing on the burying-place of a man or woman of the early Iron people. They were the people who occupied England at the time of the Roman invasion. Cæsar did not meet savages, but a people with smart weapons, iron swords, chariots beautifully ornamented, and, he believed, efficacious and altogether an armament which even the Roman legion found it difficult to fight against. Cæsar met with such a reception that he never attempted it again, and it was not until Claudius that the Romans conquered the country, not only with a good courage but with good weapons. They had spear-heads of iron and shields made of wood, covered with leather, and in some cases further covered with bronze ornamentation in a variety of ways and set in some instances with coral and very frequently with enamel. These people were a long-headed people, very much like the people of the Stone period. It had struck him, and he had seen nothing which induced him to take a contrary view to what he took many years ago, that the growth of the Iron people was not due to any further invasion, but that they were the people who had been conquered by the Bronze people, who had reasserted themselves. He thought he might state without any hesitation whatever that the use of iron came in England 200 or 300 years before Christ. He thought that the facts might be taken as conclusive that about 250 B.C. iron succeeded bronze. These people were extremely skilful in the manufacture of all kinds of metallic processes. But, besides that, they had enamel. He did not think that enamel originated here; it was not known where it originated, but it was used to a very large extent by the early Iron people, from whom the Romans copied it. Up to that day very little was known of the people who threw those mounds up. They were called the Danes' Graves, but that meant nothing whatever. We had other places attributed to the Danes which had nothing whatever to do with them. We had Danes Dike and the Grim's Graves, which he opened in Norfolk. The fact was that our Teutonic ancestors, when they came across anything they did not understand, very naturally attributed it to either the Danes, from whom they suffered considerably, or to the Devil, whom they feared. Until that day no one had been able to say positively what these graves at Kilham were. Thirty years ago he opened some, and he acted in a most foolish manner. He opened some of the little ones, and found only a few ornaments and pottery, and a few rusted bits of iron, which told nothing whatever. Therefore, he could not come to any certain conclusion,

although he had held the opinion for many years that they were the burying-places of people of the early Iron period. He was led to the opinion by an iron bracelet in the Ashmolean Museum, Oxford, found in one of the graves at Kilham. That was emphatically an armlet of the early Iron period. Now all doubts had been set at rest entirely. Mr. Mortimer had found a very beautiful bronze pin enamelled. It was a specimen of early British enamelling, and a type quite peculiar to the early Iron period. It had a peculiar twist in the shank, which made it quite conclusive. Here they had behind them much more conclusive evidence. In the graves they had the remains of a chariot. The chariot was an important element in British warfare. Caesar found it a very important means of offence, especially when scythes were fixed to the wheels. He did not know whether there was a scythe on the chariot now discovered. He had opened two other graves, at Arras and Beverley, in which chariots had been found, and in the one at Arras there were the tyres and naves of the wheels complete. The tyres were iron, but the naves bronze. Then there was an iron mirror with bronze mountings, and curiously enough the person buried was a woman. She was no doubt a great lady, for she was buried between two pigs, to serve her in another world. There was also the end of the shank of the whip of bronze, and two or three rings from which the reins of the chariot had been carried. There was nothing of the belts and other things found with the bones at Beverley. The bones there had gone to decay, but at Arras the human bones and the pigs' bones were just as fresh as if they had been buried only 100 years. There was no trace of the horses, except the bits, therefore the man must have been buried with the chariot and his horses, represented by the wheels and the bits. Similarly at the grave at Kilham.

CLERGY AND ARTISTS' ASSOCIATION.

ON Monday the Bishop of Rochester presided over the second general meeting of this Association, held at Victoria Tower Chambers, Millbank Street, Westminster. The Chairman said the Association began its operations a little more than a year ago on a very small scale, and it was gradually gaining the support and confidence of the public. Its object was to enable the clergy to approach the artist more directly with the idea of obtaining the direct work of the artist in the decoration of churches, and of forming a centre where examples of artists' work executed in churches could be seen and information given. Within the past year the membership had increased by about fifty. The growth of the work was very evident, and the demands made upon the Association were steadily increasing. Mr. R. Hallward, hon. secretary, gave a detailed account of the progress of the work of the Association, the members of which now amounted to about 150. The income last year was about 180*l*. A discussion upon the question of work at future conferences terminated the proceedings.

TESSERÆ.

Peculiarities of Normandy Churches.

NORMANDY in the twelfth century was an English province. The difference in style between that and the other districts, even in the north of France, and joining on to it, was far more marked than between Normandy and England; even the very plans of the churches are quite distinct. In England and in Normandy we have long narrow naves, with side aisles, also generally narrow in the earlier buildings. In Anjou and Poitou the style of that period is called by the French antiquaries the "Plantagenet style," and correctly, as matter of history; but the name has not been adopted by English writers, and we have no similar building in England. Neither in Normandy nor in England was the central space, whether choir or nave, vaulted over before the middle of that century. The vaults over the central space of the abbey churches at Caen are additions to the original building almost a century later. At Sens, also, the central vaults were added after the great fire in 1184, that is, just after Canterbury was finished. In Normandy the round abacus of the capitals is common; it is rarely found in any other part of France, and yet it is almost a necessary feature of the Gothic style. The plain round moulded capitals also occur, though not so frequently as in England. Detached shafts to the jambs of windows or doorways are common in both windows of two lights and of three lights, separated by mullions, and without tracery at first, are also both English and Norman. In an architectural point of view, Normandy may be considered as a part of England, from the time of the Conquest to that of King John, that is, during the whole period of the Anglo-Norman style.

Greek Vases.

All Greek fictile vases were formed, with the help of a potter's wheel, out of a lump of moist clay, and subsequently baked in a furnace. Their surface was ornamented with a variety of designs painted on the clay, and in some instances incised or modelled. The subjects with which these vases are decorated are for the most part derived from the divine or heroic legends of the Greeks. Many of the incidents represented belong to well known myths. Others are chosen from legends which, though they may have been quite familiar to the Greek mind, are not so well known to us. Though it may be assumed that the greater part of the compositions depicted on vases represent mythical incidents, or have a symbolical import, there are some which seem to be simply scenes from real life. Thus we find many subjects relating to the chase, the public games or the indoor occupation of the women which cannot be connected with any known myth. These representations of the actual life of the Greeks have a special interest as evidence of their manners and customs. We learn from vases many curious particulars in reference to the Hellenic ritual, games, festivities and domestic life; and we have representations of many products, instruments and technical processes of the mechanical arts. These curious details may be studied not only in the vase pictures which seem to represent scenes of real life, but also in those which are certainly mythical; because in Greek art, as in Greek poetry, the gods and heroes are constantly represented in the figure and attire of mortals, and in the legends relating to them many incidents and traits are borrowed from real life. Hence, in vase pictures, whether gods, heroes or mortals are represented, we find a general similarity in the costume and character of the figures. The relative antiquity of the different classes of vases may be determined approximately by the style, and in the case of the inscribed vases by the shapes of the letters, mode of writing, orthography and grammatical forms.

Renaissance Architecture.

The especial struggle made by the Renaissance architects developing out of Gothic architecture was towards the increase of domestic enjoyment, through the hall, the hearth and the home; while the tendency of the Italian Renaissance architects developing out of culture direct from classicality was towards that semi-public domesticity which took the form of the more stately palace. That modification of the later Italian architecture which became popular in France from the time of Louis XIV. onwards was essentially aristocratic and courtly. Vast in extent but poor in proportions, the architecture of the Frenchman of Louis XIV.'s time was no bad reflection of the characteristics of Louis himself—at once pretentious, and incompetent to convey any other idea than that of inability to rise to the grandeur which he felt it his duty to aim at, even while unable to attain it. In most of our modern architecture, up to within a comparatively recent period, men throughout Europe have seemed content to follow a sort of accidental system based, not upon the study of principles, but upon the works of any fashionable or successful contemporary. A species of rule of thumb, varied only by the endeavour to do a little better than some immediate predecessor, seems to have ruled very generally, and it was not until periods of revolution had wakened men to a free assertion of their rights of intellectual judgment in all directions that an effort was made to throw off the feeble shackles of an empty academic system. With this free trade of thought sprang up a respect for many a long-forgotten mind, whose existence beyond the pale of the academic curriculum had doomed his life and labours to all but oblivion. With new respect for such men came new respects for old systems, and with respect for old systems, for old monuments. The reaction from the destruction which took place in revolution was naturally increased care for all that revolution had spared.

Roman Grouping.

The Romans seem to have affected the practice of grouping buildings together as features in one general symmetrical plan. Their temples and basilicas were frequently placed, as the principal architectural objects, at the extremity of a forum or other regular area enclosed with colonnades. The Temple of Nerva stood at one end of, and partly projected into an enclosure (measuring about 360 by 160 feet), the entrance end of which had five open arches, and the sides were formed by screen walls, decorated with Corinthian pilasters and columns immediately before them, over which the entablature formed breaks. Of Trajan's forum, which was surrounded not only by colonnades but various stately edifices, nothing now remains except the celebrated triumphal column that occupied its centre, and which, so placed as a principal object, must have heightened the splendour of the whole. Like that of Nerva, the Temple of Antoninus and Faustina was placed at one end of a court of moderate dimensions, whose sides were adorned with coupled columns placed immediately against the walls; and only the portico part of the temple (a Corinthian hexastyle, triprostyle) advanced into

the enclosed area in front. The forum of Caracalla was nearly a square, entirely surrounded by arcades, presenting thirteen arches on each of the longer and eleven on each of the shorter sides. In the centre was a Corinthian temple very similar in plan to the Pantheon, with a hexastyle, triprostyle portico in front, and remarkable for having inner columns behind the second from each angle, so that there was a double range of them at each end, and the central space within the portico was a perfect square equal to three intercolumns. Unlike those of Greece, peripteral temples were of comparatively rare occurrence among the Romans; they were mostly prostyle, the portico being attached only in continuation of the cella, whose walls formed the flanks of the building, though the order of the portico was frequently continued along them either in half-columns or pilasters. Such is the plan of that celebrated one at Nîmes, known by the name of the *Maison Carrée*, which is a Corinthian hexastyle, pseudo-peripteral, the cella being ornamented with attached columns, thereby making ten intercolumns on each flank, three of which are open, or belong to the portico, which latter is accordingly triprostyle. The Corinthian temple at Assisi was similar in plan, except that it was not pseudo-peripteral, the sides of the cella being plain. That of *Fortuna Virilis* at Rome was an Ionic tetrastyle, diprostyle and pseudo-peripteral. Besides contributing to variety, temples of this kind possess a certain variety of effect in themselves, owing to the depth of the portico and the contrast between that part and the cella.

Instruments and Geometry.

It is usual to say that the rule and compasses are the instruments of Euclid's geometry, which is not altogether correct, unless it be remembered that with neither ruler nor compasses is a straight line allowed to be transferred, of a given length, from one part of space to another. It is a plain ruler, whose ends are not allowed to be touched, and compasses which close the moment they are taken off the paper, of which the Greek geometry permits the use. It is altogether uncertain by whom these restrictive postulates were introduced, but it must have been before the time of Plato, who was contemporary with (if he did not come after) the introduction of those problems whose difficulty depends upon the restrictions. We may here observe that in actual construction the ruler might have been dispensed with. It was reserved for an Italian abbé at the end of the eighteenth century, when all who studied geometry had for two thousand years admired the smallness of the bases on which its conclusions are built, to inquire whether, small as they were, less would not have been sufficient. In Mascheroni's "*Geometria del Compassa*," published at Pavia in 1797, it is shown that all the fundamental constructions of geometry can be made without the necessity of determining any point by the intersections of straight lines; that is, by using only those of circles. This singular and very original work was translated into French, and published at Paris in 1798 and 1828.

Coloured Statuary.

The influence of the material is everywhere evident in Greek art. As the Egyptians did not paint their statues of granite or porphyry, but only those of wood, limestone, or sandstone, so the Greeks, as soon as they began to employ marble and ivory, which is of a nature allied to marble, discovered the true law for the application of colour—a law which they never afterwards transgressed. It corresponds precisely with the law which regulates the use of colour in the marble temples. As in the marble temple the main body of the temple was white, and only particular parts such as the metopes, the triglyphs, the cornice and the ornaments of the ceiling were brought into prominence by means of colour, partly to heighten the effect of the pure white by a lively contrast, partly to secure for the sculpture an effective background, so in the sphere of plastic art the body was kept quite pure, and only certain portions of the face, which in the natural human form are sharply distinguished from the prevailing flesh-tone by an intensified colouring, received additional prominence. The full use of colour takes place only in the dress which certainly is sometimes painted, not merely along the borders, but throughout, as in the Panathenaic procession of the Parthenon cella-frieze. The decoration supplied by colour marks the robe emphatically as ornament, and distinguishes it from the more profoundly significant corporeal forms; while the wreaths, diadems, weapons and symbolic attributes of gilded metal all serve to strengthen the affinity between plastic and living forms, as the shields won in battle which were fastened to the architraves of the temple connected the ideal world of architecture with real life. Nor need we be afraid of finding that bronze statuary transgresses this well-defined law. The bronze statue is by its very nature still further removed from artificial colouring. Here again, accordingly, we find only eyes, lips and hair, and some parts of the dress brought into prominence by means of gold, silver and precious stones, but so far from any attempt at deceptive imitation being made, the lips, for example, are regularly plated

white with silver. When the anecdotes of art, then, tell us of the sun-burnt skin of the statues of the athletes, of the blush on the cheek of Athamas, of the deadly paleness on the countenance of Jocasta, or even of the red on the cheeks of the Lemnian Athene of Phidias, such stories may help to give us a lively conception of the high perfection to which the art of fusing metals had been brought, and may show a certain amount of degeneracy in that art; but, like the descriptions of Callistratus, they are for the most part to be considered as strongly tinged with rhetorical exaggeration. The ancients themselves put a high value on the fine green tone of the patina produced by oxidation; it is the *nobilis ærugo* of Horace. But how could they do so if they at the same time demanded from the bronze deceptive resemblance?

The Nude in Greek Art.

The kings, princesses and heroes of a Corneille and Voltaire never forget their rank in the most vehement passion, and they put off their humanity far sooner than their dignity. They are like the kings and emperors in the old picture-books, who go to bed with their crowns on. How different with the Greeks and those of the moderns who have composed in their spirit. The Greek is never ashamed of nature; he allows to the sensuousness its full rights, and yet is always secure from being overcome by it. His deeper and more correct intellect permits him to distinguish the contingent, which a bad taste magnifies, from the necessary. But all in man that is not humanity is contingent. The Grecian artist who has to represent a Laocoon, a Niobe, a Philactetes, knows of no princess, no king, and no king's son; he busies himself only with men. For this reason the wise sculptor throws aside the vestment and shows us only naked figures, although he knows very well that this does not occur in actual life. He esteems clothing as something contingent, to which the necessary need never be postponed, and the laws of propriety or need are not the laws of art. The sculptor should and will show us men, and garments only conceal them; he is right, then, in throwing them aside.

Theories of the Beautiful.

Alison would make the beautiful simply consist in association; Burke would be content to identify the beautiful with the merely agreeable, and would call sweetness, for example, beautiful to the taste, in the same sense in which a flower, a picture, or the window of a Gothic cathedral is beautiful to the sight; Dugald Stewart goes far towards identifying the beautiful with the useful or the appropriate, and would explain it on the theory of an adaptation of means to ends; Sir Joshua Reynolds held the beautiful to consist in a mean between two extremes, so that the Greek nose, for example, would be beautiful, as being the due medium between that of the Roman and the negro; and, in short, interpreted the beautiful simply on a theory of habit, even to the extent of believing that if that which we now are accustomed to call ugliness had predominated in the world we should feel in it the same pleasure which we now do in the beautiful. There is one theory which has the singular recommendation of being at once the earliest and the latest propounded on this subject, that of the Greek school of philosophy—of St. Augustine, of Coleridge, and of the Père André—viz. the doctrine that beauty is unity, or to express it as is occasionally done, is "plurality in unity," or the combination of the many into one, so as to form a whole. The objection to this definition is the vagueness of the word unity, which may signify anything or nothing. Plotinus says the triangle is the first-born of beauty, as being the most elementary combination possible of the "many" to form "one." Now it is obvious to ask if the connection of three lines into a definite figure is a creation of the beautiful, as being the union into a whole of three parts, what are we to say to the figure resulting from the union of three lines of unequal length? The scalene triangle, which is the figure in question, is certainly not beautiful, though it realises the definition, or seems to do so, and consequently the definition itself is either obscure or not true.

Street Lighting.

It is certain from Jerome that the streets of Antioch were lighted, and it is probable that Rome and a few other cities had some streets lighted. Lamps were suspended near the baths by ropes, but the classical ancients used lights in going home. Beckman says that Paris was the first of modern cities which was lighted, at the beginning of the sixteenth century, because the city was infested with street robbers and incendiaries. This was merely an order for the inhabitants to keep from 9 P.M. a light burning before the windows which fronted the streets. In 1558 fallots or cressets were erected at the corners of streets, three in different parts of a long street, but in the same year this light was changed for lanterns, like the modern. In 1667 lighting the streets was put upon its present footing. In 1414 lanterns were ordered to be hung out in London between Hallowtide and Candlemas. Several attempts were afterwards made, but none succeeded before the application to Parliament in 1744 and 1766. The reverberating lamp was the invention

of Bourgeois de Château-bianc in 1766. Beckman furthermore gives an account at what periods the several cities of Europe were lighted. Pall Mall was illuminated with the new invention of gaslights in or about 1806 or 1807.

Liskeard Church Tower.

SIR,—I am not in a position to fully go into the letter of Mr. Geo. H. Fellowes Prynne of July 5 in *The Architect*, owing to the fact of our tower faculty being under reconsideration. We have had a great number of thoughts stated and restated by Mr. Prynne about this *semi*-Norman tower. Many architects have paid this old church a visit—their *bona fide* opinions I courted in my first letter. Mr. Prynne has dished up for us this tower in your paper, in the *Western Morning News*, in the *Church in the West*, in the *Builder*, and I know not where, until it has become nauseous. Well, let us look at this grand old tower of 600 years' standing. 1. We will look at the west side, to find nothing but some grotesque leads, and these are by some not even allowed a Norman birth. We go to the south side, and we find very little of the Norman work, and that little is covered over with blue slate slabs, cramped together, and then stuccoed. You look at the east side. To do that you have to climb the roof of the nave, and then you are vastly disappointed. Take the north side. There you have your reward in the sight of a heap of small rubble stones, three small and very plain windows. The fact is the bulk of the tower is of the seventeenth century. Mr. Prynne estimates the cost of repairing at 800*l.*, for which we shall have a patched-up tower, bolted with eight iron rods, supported by two buttresses, slabbed with granite blocks to harmonise with the seventeenth-century west end for "many years," "for many generations." The repairing-patching-up done by the seventeenth-century men is not enough. We must spend 800*l.*, and hand down to the future the burden of repairing-patching-up again. I am human, and, therefore, cannot help thinking that Mr. Prynne is disappointed in our refusing to follow his wisdom. He knows best. For myself, I have no intention of being a party to such waste of money. Let us go forward.

Yes, it is true Miss Pedler, in the year 1890, left 1,000*l.* towards the rebuilding of this tower—not repairing-patching-up—on our raising 2,000*l.* by 1900, failing which this 1,000*l.* must gravitate to Truro Cathedral, and augment her former gifts of 13,000*l.* (I am told 15,000*l.*) to that building.

Miss Pedler was guided in this her gift by the opinions of gentlemen of well-known standing in the architectural world. The rebuilding scheme of this tower is not the dream of a night, but the dream of 400 years. The gentlemen of the fifteenth century who nobly built this large Perpendicular nave—having taken down the small Norman nave—would have erected a tower worthy of their new nave had their cash been sufficient. Had they meant the Norman tower to have remained, why did they not rebuild their Norman nave? If the men of 1627 had dreamt of the Norman tower remaining they would have done their repairs and rebuilding in the Norman. The fifteenth-century architects were prevented from carrying out their noble scheme from want of cash, not from want of ability or desire, but from want of the needful money. My supposition is quite as sound as that put forth by Mr. Prynne.

Mr. Prynne says "I hope the Chancellor will not insist on having the tower rebuilt as at present, as it can well be repaired as before stated." No one ever said it could not be repaired. You can repair any building at any cost, but the wisdom of it is another thing. Mr. Prynne says it can "well"; here we differ. To spend 1*l.* 10*s.* on repairing a worn-out and useless suit of clothes when 3*l.* will buy you a new suit is not commendable. You can do what you like with your own money, but you have no right to ask others to give you their money to do a work in which you have reasonable doubts. I say, too, that Mr. Prynne is *ultra vires* in his expressions. Suppose we say, Yes, repair at a cost of (at least) 800*l.* Who will or has to find the money? Mr. Prynne? The Royal Institute of British Architects (from whom we had last week a long letter on vandalism), or any other society? I would like to say more, but I must remember "*sub judice*." I object to the photo of our church tower in your issue of July 9. It is cleverly done. The south porch is dragged in to cover the blue slabbed-stuccoed condition of a portion of the tower, and the long vertical crack is omitted.

I have no hesitation, for my own part, in saying, for the benefit of Mr. Prynne and the few of his school, that without the incentive aid of Miss Pedler's 1,000*l.* there would be no prospect of either repairing this tower, at half of the cost estimated by Mr. Prynne, or of rebuilding this tower, incorporating, as we have stated and restated, the few precious stones of the Normans, of the Perpendiculars, of every sound

stone of this tower into the proposed semi-new tower. Liskeard is not the wealthy town of twenty-five years ago; but with a strong effort, with much self-denial—and we are all unanimous—we can build a tower "more worthy of this church" to cost not less than 3,000*l.* by our raising not less than 2,000*l.* I also candidly acknowledge that Mr. Prynne has not furthered our scheme, but no doubt has influenced many against us. Be that as it may, we paid Mr. Prynne for his visit here and report; having done that, we are under no further obligation to him. We shall try to do what we deem best, guided by the powers under whom we are.—Faithfully yours, J. NORRIS.

July 20, 1897.

Sydney Statuary.

SIR,—I notice in your issue of July 16 a reproduction of the selected group of statuary for the Sydney markets, together with a few remarks thereon. As there are several inaccuracies, I trust you will allow me to correct them.

As I, in conjunction with Mr. Illingworth, was one of the competitors, I am in a position to state the actual facts. For this same reason I shall not attempt to criticise the Council's selection.

Where your account is incorrect is—

1. There were no prizes offered, at which we all greatly demurred.

2. Instead of three competitors, there were sixteen or more.

3. The models submitted were in plaster or wax. Two insignificant ones might have been in clay.

4. Since leaving Sydney I have been informed that Mr. McIntosh contracts to supply three groups for 3,150*l.*, not two, as you stated. The facts are as follows:—The latter part of last year the Council voted 3,000*l.* to erect a single group of statuary for the new markets. Some time later we were invited by advertisement to send in sketch models with tenders, stating price in either bronze, marble or freestone. There was nothing said about three groups, but we were told *ex officio* that two more would be required later. The group was to be 14 feet 6 inches high and 14 feet 6 inches at the base. It was to be erected 50 feet high, fronting a narrow street. No size was stated for the models, and no material was mentioned. About 16 models were sent in, ranging from small sketches to quarter-size models, and coloured white, pink, terra-cotta and bronze. Some of the competitors spent months of time and a serious amount of money to perfect their groups. Ours cost us 50*l.* in hard cash, and about three months' actual labour. The designs were exhibited in the vestibule of the Sydney Town Hall, which is lighted only by a circular light at the top, and has the dim religious light generally connected with a cathedral or cloister. This made it bad for some, as bronze was most in favour, and groups were modelled to be looked at from below. Finally, after much delay, the Council appointed the city architect, the Government architect and the mayor to select three groups, out of which the final selection was to be made. After this I have since heard that Mr. McIntosh was selected, and contracts to supply three groups in marble for 3,150*l.*—Yours faithfully, HERBERT C. ODLING.

London: July 19, 1897.

GENERAL.

Mr. Reginald St. A. Roumieu has been selected as surveyor to the Girdlers' Company. He has also been appointed hon. architect and surveyor to the School for the Indigent Blind, St. George's Fields, S.E., a corporation established by Royal Charter.

The Annual Report of the Palestine Exploration Fund announces that the limits of the Pool of Siloam have been determined, and portions of the rock-hewn steps which led down to it have been found. The church which was known to have existed at Siloam has been discovered, and its plan, which presents many features of interest, has been ascertained. The paved street which has been followed a long distance up the Tyropeon Valley is apparently that by which the pilgrim Antoninus (570 A.D.) descended from the "Double Gate" or "Triple Gate" of the Haram to Siloam.

The New Iron Railway Bridge over the Adour at Tarbes broke down while being tested on Saturday. Two engines and three trucks containing twenty-five persons fell into the river. Some were seriously injured, but it is hoped that they will recover.

The Subject for the Grand Prix in Painting in the Ecole des Beaux-Arts is *Vulcan aided by Force and Violence enchain-ing Prometheus to one of the rocks of the Caucasus*.

A Memorial Tablet has been fixed on the wall of the Ecole Normale in the Rue d'Ulm, Paris, recording the discoveries of Pasteur in the laboratory of the building, from 1857 to 1885. The portrait of the chemist is by M. Auguste Patey.

A Sum of more than 15,000*l.* is now available to establish a professorship of Public Health and Sanitary Science in the University of Edinburgh.

The Architect.

THE WEEK.

THE competitors for the Cardiff Town Hall will have the advantage of Mr. WATERHOUSE's services as assessor. It is arranged to pay him a fee of 300 guineas for the troublesome work of examining the designs. Mr. WATERHOUSE suggested that it was undesirable that the proposed 5 per cent. commission to be received by the successful competitor should include travelling expenses. Every inducement should be afforded to the architect to devote as much time as possible for personal supervision of the building operations, and nothing should be done to handicap the ablest architects obtainable in the country. The committee have agreed to the proposal, and, as Mr. WATERHOUSE has succeeded in Cardiff, there cannot be much difficulty in obtaining a similar concession in other towns. Mr. WATERHOUSE's recommendation that the time for sending in designs should be extended to December 4 was also adopted.

THE perversity of a party of members of the London County Council was again exemplified on Tuesday. After the late scandals, and the voting which followed, the works committee was supposed to have no more than a nominal existence. Decency dictated also that the supporters of so questionable an institution would henceforth avoid any attempt to renew arrangements which have brought discredit on the system of local government. But on Tuesday advantage was taken of the absence of members who are in favour of economy. Works were grasped which are beyond the capacity of the works department as it is now constituted. There are to be at least three more undertakings, for which the people of the Metropolis may be certain they will have to waste a higher sum than would satisfy a contractor as his profit. At Millbank sewers and roads are to be constructed on the amateur system at a cost of 11,653*l.*; a block of dwellings is to be raised in Boundary Street area for which the estimate is 17,943*l.*, and another costing 5,460*l.*, or in other words 34,453*l.* can be expended, with the certainty of a further outlay, in order to gratify a party that has been tested and failed. As showing the absurdity of the arrangement, there are two other blocks in Boundary Street area with which the committee dare not meddle, as the estimates are supposed to be insufficient. If they have the hardihood to try their administrative ability on two blocks, why should they be daunted with an additional two? The fear suggests that the Council's estimates are not prepared on a uniform system, and that is enough to excite grave reflections in the public mind.

THE contest on Saturday last for the seat in the Académie des Beaux-Arts, rendered vacant by the death of M. FRANÇAIS, the landscapist, was really confined to M. HARPIGNIES, another landscapist, and M. VOLLON, the painter of still life, although MM. BUSSON, AIMÉ MOROT, DAGNAN-BOUVERET, FRANÇOIS FLAMENG and A. MAIGNAN were also inscribed as candidates. Thirty-five Academicians took part in the voting. After several attempts, in which the required eighteen votes were not obtained by anyone, it was found that for M. HARPIGNIES there were seventeen votes, and for M. VOLLON sixteen, while M. MOROT attracted two. On the retirement of the last, his supporters gave their votes to M. VOLLON, and the struggle was decided. The new Academician is a native of Lyons, and is the most successful of the French painters of still life. His splendid colour and the brilliant accessories he introduces make his pictures dangerous neighbours in an exhibition. It is remarkable that in England his class of work is rarely attempted, although it affords exceptional opportunities for skill in colour and arrangement. One of M. ANTOINE VOLLON's works would be not only a novelty in an Academy exhibition, but an experiment that would determine whether there was a market for refined "still life" in England.

THE international congress on the subject of fires which it is proposed to hold in Paris is approved by several ministers, senators, deputies and municipal councillors.

But what gives the project importance is the support it has received from architects. Among them are MM. BOUVARD (Inspecteur Général of the Service d'Architecture of the City of Paris), VAUDREMER, CHARLES GARNIER, LEGROS ("Architecte-Voyer en chef"), PIERRON ("Architecte-Voyer en Chef, adjoint"), and BUNEL (Architecte en Chef to the Prefecture of Police). There are also several professors of medicine and of various sciences. At the present time Paris is certainly the most eligible place for the discussion of the subject. From their peculiar construction there is less danger in the houses of fatal or dangerous conflagrations than in most other cities. The general confidence in the safety of every structure thus removes all anxiety when sheds are run up like that for the bazaar in the Rue Jean Gougon. But the Municipal Council will have to insist on less flimsy work on other occasions; and, moreover, it will be necessary to provide an organisation and appliances which will be equal to emergencies. For that purpose, as Mr. HOARE, the English representative of the Congress, says in his letter:—"France requires in this matter to get assistance outside her own country, and nowhere can she get it better than in England."

THE affection of Americans for England will be often appealed to if Devizes Castle and the demesne around should be acquired by a purchaser from the States. Advertisements of the forthcoming sale have appeared in New York papers. What is more important, the influence of Mr. A. J. BLOOR, the architect, has been obtained, and he descants on the interest attached to a building which was the dower-house of twelve English queens, and was protected by a moat, "the waters of which once engulfed many an armour-weighted besieger." The owner, it appears, is eager to have a successor who will do justice to the place, and, says Mr. BLOOR, "I think there are, somewhere between the Atlantic and Pacific seaboard, men in this community who have both the wealth and the sentiment to indulge in, and to appreciate in all its bearings, the possession of such a place, and among these bearings I count as not the least the owner's opportunities for helping to foster the brotherhood of the English-speaking peoples, and through them the civilisation and best interests of the world." In that desire we join, and indeed it would be satisfactory if several additional Americans could be induced to settle among us.

AN extraordinary case has been decided by the Supreme Court of New Jersey. It seems that a new city hall was lately built in Jersey City, and among its decorations were intended to be some "allegorical groups." These were included in the contract, but the specification required that they should be executed "in an artistic manner." When these groups, which were of sheet-metal, were put in place, they failed to satisfy the committee of the City Government, who found a statue of FLORA, which appeared in one of the groups, "out of all proportion to the human figure," and, in general, considered the "sculptures" to be "a disgrace, rather than an ornament" to the building. They accordingly refused to accept them as "artistic" within the meaning of the contract, and notified the contractor to furnish others. This he did, protesting, however, that the original groups had been made "by a reputable firm in Ohio," and were in accordance with the specification, and when the committee were at last satisfied, he sent in a bill for extra work, including these and some other things, to the amount of 26,000 dols. As the largest item was that relating to the "sculptures," the important question was whether those originally furnished were "artistic" within the meaning of the contract. As the person who drew this up was so incautious as not to specify who should be the judge of their artistic quality, the decision came upon the jury, which, naturally enough, concluded that the contractor had done his duty in this regard by ordering them of a "reputable firm," and brought in a verdict in his favour. The moral of this story is, says the *American Architect*, that if an owner or architect wishes to get anything "artistic" under a building contract, he should specify in the contract who shall be the judge of the artistic quality of the object. If he does not do this, the contractor's opinion is, legally, just as good as his in regard to its merits, and, if they cannot agree, a jury must decide between them.

OPERA-HOUSES AND THEATRES.*

THE first volume of Mr. SACHS'S stately work on theatres and opera-houses revealed so excellent a plan, the utmost we can expect from succeeding volumes is to have a correspondence between them and it. There is no doubt about the second volume attaining the standard originally proposed. The plates are again careful copies of the architects' geometrical drawings. They exhibit a class of buildings having much in common with other varieties of modern work, while they have their own peculiarities. The use of the volume is not therefore confined to builders of theatres. For ornament especially many of the plates will be found to abound in suggestions. With so many excellent precedents at the command of English architects we hope soon to have an end of the terribly commonplace theatres which so often deter lovers of architecture from seeing plays. Beside so much inane pretension as can be found in London and provincial towns, a canvas booth almost rises to the dignity of a work of art, and the O of Bankside becomes one of the wonders of architecture. We have no wish to see anybody suffer financial loss, but it would be an advantage if three-fourths of the theatres constructed during the last quarter of a century were consumed and left not a wrack behind.

What makes buildings of the class more terrible is the apprehension that they are inevitable. According to the President of the Royal Academy, "a strong feeling for the higher forms of art has never existed in this country, or, rather, the artistic faculty has never in our race risen of its own accord towards the higher forms of art." The majority of the British theatres are evidence of an indifference to form which is not found elsewhere. What is the cause? It cannot always arise from some inherent weakness of the race. Mr. SACHS in his first volume kept together examples of Teutonic or of Anglo-Saxon origin, while in the second playhouses from Latin countries were to appear. His belief is that "little if anything is to be learnt from modern theatres in France, Italy and Spain; taken generally, the examples from countries subject to Teutonic and Anglo-Saxon influences alone show a marked development in theatre construction." That arrangement could not be rigorously carried out. English theatres appear in both volumes, and it must be said they do not surpass the Latin or the Teutonic examples.

The plates in the second volume begin with the Paris Opera House. There is no modern building which so quickly fascinates a stranger, and by a sort of perversity not one is more severely criticised. It is said to be of a debased Roman type, the exterior is considered too low, the interior too high, there is too much gilding according to some, too much sculpture and painting according to others, the eye is said to be too distracted to enjoy the living pictures behind the footlights and repose becomes impossible. All these remarks are only efforts to account for the sway which the building exercises. The Opera House was erected at a time when costliness was supposed to be a virtue and display was a necessity of life. It exemplified as well as is possible in a building the imperial principle which in 1861 was believed to be enduring in France. It still retains some of the emblems which made it more expressive, but others are now wanting which would have given emphasis to that expression. It was accepted as more than a theatre both by those who lived on Napoleonism and their enemies. When, therefore, dark fluid was cast on the group of *The Dance*, all parties accepted the stain as the handwriting on the wall—an omen of the overthrow of the Governmental system. Mr. SACHS renders more justice to the architect than is usual with critics who are less competent to judge. In one place he says:—

There is one feature which, though characteristic of his work, has not been generally recognised, namely, that Garnier designed with a very distinct purpose in his mind, that every line in his sketches and drawings was based on a system, and what may appear eccentric or even ill-advised in the architectural rendering was in no case the outcome of an unthinking mood. We find in Garnier, in fact, an architect who most

studiously examined the requirements of his client and the public taste of the period for which he had to cater. He was no mere talented artist who, as is often the case, designs spontaneously but without method. The very fact of his tour of inspection immediately after obtaining the commission speaks forcibly on this point. Combined with his natural genius and his great facility with the pencil was a power of application and, further, a strict regard for business. It is this combination that has given him the position which he holds to-day. It may appear curious to have to state so simple a fact here, but general opinion, particularly in art circles, has been disinclined to accord to Garnier anything but great talent. He has always been regarded as an artist of genius, and rarely as an architect in the fullest sense of the term, who gave equal attention to the three aspects of architecture—the business, the scientific and the art sides. Anyone who has followed the history of the Paris Opera House closely will comprehend what infinite pains the architect expended upon the most trivial technical details, and what amount of thought was, for instance, given to stage machinery, a department too generally relegated to other hands than those of the designer. It may indeed be news to some that official documents show that Charles Garnier was actually considering the resignation of his commission should the Government, his client, compel him to use in the auditorium *strapontins*, a kind of seat which he deemed a dangerous obstruction in the gangways in the event of a panic.

What St. Mary, Walbrook, is to St. Paul's, the Casino Theatre, Monte Carlo, is to the Opera House of Paris. Sculpture and painting, gold and colour in profusion, suggest wealth, as the numberless broken lines hint of the disregard of rules and precedents which wealthy gamblers can exercise. The exterior is an Italian villa embellished by French taste, or rather a combination of the Renaissance of the two countries as interpreted by M. GARNIER. It is to be regretted that a little of his spirit was not caught by M. BERNIER when designing the New Opéra Comique of Paris. The uncertainty which attended the competitions, the conflicts between officials on the subject, and the financial limitations imposed must have affected the architects who meddled with the project. Mr. SACHS is compelled to regard the building as proof of his assertion that "there has been little or no progress in France since the erection of the Paris Opera House." He adds:—"One would almost imagine on looking at the plan that the architect was unacquainted with the advance which has been made in other countries during the last few decades, and that he had overlooked the fact that his site had been the scene of a terrible fire; the isolation of staircases and the separation of the audience into sections, which are the most elementary features of the modern theatre plan, have been neglected, although the ground offered fair opportunities for skilful planning in this direction. As to the academic rendering of the exterior, its mediocre treatment can only be termed regrettable." The Eden theatre which used to stand in the neighbourhood of M. GARNIER'S opera house was mainly made up of cement and plaster over an iron skeleton, but it had a massiveness which was more suggestive of India than of France. It has now disappeared, but it was remarkable, both from the system of construction and the novelty of style which formed a pleasing sight in a city which has an excess of Renaissance façades. Mr. SACHS illustrates three Italian theatres. The Municipal Theatre of Palermo is severely classic in appearance, and would be suitable for a people who take their pleasures sadly. The Palermo building is very large, for it accommodates 3,200 people; but it would hardly be called a safe theatre owing to the character of the staircases. The architects were FILIPPO and ERNESTO BASILE; but Mr. SACHS says modern Italian theatres are generally erected by master-builders who are speculators, and who design and erect theatres for a fixed sum, and manage to do so without the aid of an architect. The "Lirico" Theatre, Milan, was constructed by ACHILLE SPONDRINI, whose organising power is greater than his knowledge of design. The building, we are told, was practically carried out without any plan, and the builder it appears did not receive much school education or technical instruction. Much better in style is the People's Theatre at Turin, of which Signor CAMILLO RICCIO was the architect, in which modern requirements have been met. The Municipal Theatre in Bilbao is like much else in Spain—that is, out of correspondence with the rest of Europe. The lowest seat is 26 feet above the

* *Modern Opera-houses and Theatres.* Examples selected from Playhouses recently erected in Europe. By Edwin O. Sachs, architect. Vol. II. With 100 plates and 95 illustrations in the text. London: B. T. Batsford.

street, and three out of the four staircases leading to the house are curvilinear in plan, but the external appearance is pleasing, and we suppose that is enough.

The Court Opera House in Vienna is worth comparing with its Paris rival. The exterior is simpler and more severe, and if there is less ornamentation in the interior, that is not altogether a disadvantage. There is only one staircase, but it is not so prominent a feature as M. GARNIER'S structure. The Vienna building was designed by VAN DER NÜLL and LICEARDSBURG, and was completed under the direction of GUGITZ and STORK. It cost half a million sterling.

Another excellent theatre is the Czech National Theatre, Prague, which has arisen on the ruins of an earlier building, which were utilised as far as possible. A handsome theatre on a triangular site is found at Salzburg. It can accommodate about a thousand spectators, and yet cost only 25,000/. The Municipal Theatre at Laibach and the "Raimund" Theatre at Vienna complete the Austrian examples; the last is an experiment, for in it the "Asphaleia" scheme of construction is adopted. The stage is lighted by side-lights, which are concealed from the audience and are supposed to be an improvement on the old footlights.

The most important of the German examples is the Municipal Opera House, Frankfort, which was opened in November 1880. Mr. SACHS says he knows of no playhouse of an earlier date in which the same clearness of plan and the same grasp of the requirements of the audience as regards accommodation are manifested. Care is taken to express the difference between the auditorium and stage and the administrative parts. The building cost 230,000/., and those who praise foreign architects for economy may be glad to know it was stipulated originally that the building was not to cost more than 60,000/. HEINRICH SEELING is an advanced architect whose name is associated with several German theatres. Mr. SACHS introduces his buildings at Essen, Rostock and Bromburg. It is considered that SEELING'S work "particularly deserves the attention of English architects, as many of the features which distinguish his buildings could, subject, of course, to modification, be adapted to the requirements of larger private establishments in this country." The "Lessing" Theatre in Berlin is a private speculation. The exterior is suggestive of machine work, but within it is excellent for hearing and seeing, and the staircase is sufficiently capacious to give safety in a time of panic. It accommodates an audience of 1,160, and the cost was 40,000/.

The next section deals with modern English theatres. The first shown is the new Her Majesty's. What Mr. SACHS says of the architect, the late C. J. PHIPPS, is marked by leniency:—

With his departure we have lost a man who has excelled in his specialty to an extent that can scarcely be understood by an outsider. He had been able to satisfy the requirements of the typical theatrical speculator, who primarily demands the greatest accommodation in a limited space at as low a cost as possible, and, what is more, he enjoyed full confidence, since no one had cause to fear any inclination on his part to incur expenditure merely in the interests of art. I hold that the deceased could have achieved far better work from an artist's point of view; but had he sought to do this his large practice would have dwindled, and he would not have retained the support of those whose financial aid was necessary for the development of his schemes. It is, alas, a sad fact, but one that is only too true. The theatre architect who aspires to treat his work from a more ideal standpoint would not, in London at least, find favour with those promoters who are responsible for the origin of the majority of our playhouses, unless they were convinced that the higher style would cost neither extra time nor money, or that if put to a greater expense they would be amply recouped by the greater popularity of the house with the general public.

Mr. PHIPPS'S Lyric Theatre is also illustrated, and he was to some extent responsible for the Garrick Theatre, originally designed by Mr. WALTER EMDEN. The Empire Theatre has undergone several transformations. When it was handed over to the late Mr. T. VERITY, it was no easy task to make it commodious, attractive and profitable. The results testify to his skill, and the later work is also creditable to the good taste of his son, Mr. F. T. VERITY. According to Mr. SACHS, money could be saved if in the back of the house modern stage machinery were freely introduced.

Another London example of a variety theatre is the Oxford, which is also successful in accommodating crowds. Mr. SACHS' awards merited praise to Mr. UNSWORTH'S Memorial Theatre at Stratford-on-Avon. Having the advantage of novelty, it might be supposed that speculators would be found to venture on the adoption of a similar style for a new theatre, but conventionalism is very strong in theatrical affairs. The building is unique as an application of Gothic, and we are afraid will long remain so. The Grand Theatre, Leeds, like the Stratford building, forms a group. It was designed by Mr. GEORGE CORSON, and is a good example of a comfortable theatre, where all the spectators are able to enjoy themselves.

The English series is brought to a close by Mr. RÜNTZ'S new theatre at Cambridge. Mr. SACHS does not exaggerate when he says "it is one of the most important instances of recent theatre construction, since we find in it, for once, a playhouse which, though essentially a commercial establishment and situated on a piece of back land, revives in every detail evidence that the greatest possible pains have been taken to give it an architectural rendering fully in accord with its purpose." That judgment would be confirmed by our readers who have seen the illustrations we have published of the building.

It is a long way from Cambridge to Athens. The next building is the National Theatre in the Grecian capital, which was designed by ERNEST ZILLER, a German architect. It is classic, although more suggestive of Berlin than of Athens. Among the peculiarities are the treatment of the front of the second tier as a balustrade and the absence of a moulded frame from the proscenium.

The remaining examples are the Municipal Theatre, Rotterdam, the National Theatre, Bucharest, the Municipal Theatre, Geneva, and the Municipal Theatre, Zurich.

It will be seen that Mr. SACHS has sought after variety in his volume, and has succeeded. By itself it is almost enough to equip an architect who desires to design theatres; but when the information respecting details which will be furnished by the third volume is added, the subscribers will be in a fair way to be qualified as experts.

The construction of theatres is not only an interesting subject for architects, it is one which should be encouraged by statesmen and all who wish to have the tedium of life made less oppressive. But there is another side to the subject. The life of a theatre may be assumed to be of the briefest. In a separate volume published by Messrs. C. & E. LAYTON, entitled "Fires and Public Entertainments," Mr. SACHS has with great industry collected particulars of the fires which are known to have occurred in buildings for amusement during the past century. They number about 1,100, and the fatalities amount to 10,000. Such statistics are appalling, but they should have the effect of putting an end to that policy of *laissez-faire* which commonly is dangerous, but in regard of building regulations is fatal. Mr. SACHS has done good work in presenting so startling a picture to the public.

CANTERBURY CATHEDRAL.—V.

FIREs and other causes made changes inevitable in Canterbury Cathedral. Apparently there would have been little difficulty in preserving the chapel of St. Benedict, wherein Archbishop BECKET was slain, in the condition it presented on December 29, 1170. The chapel of St. Blaise, which was over it, would also have interest. The alterations began soon after the martyrdom, when the column against which the Archbishop stood was removed in order to allow the people kneeling outside the chapel to see the altar erected as a memorial. This is evident from the description given by GERVASE, the monk:—

Between this space and the aforesaid apse is a solid wall, before which that glorious companion of martyrs and guest of the Apostles, the holy Thomas, fell in the body by the swords of raging men, but transmitted his unconquered soul to heaven, to be straightway crowned with the glory and honour of the eternal kingdom. This place of martyrdom is opposite to the door of the cloister, by which those four notaries of the devil entered that they might stamp the seal of the genuine prerogative of the martyr between the anvil and hammer, that is, that they might adorn the head of St. Thomas, prostrate

between the pavement and their swords, with the stamp of the Most High, the chaplet of martyrdom.

The pillar which stood in the midst of this cross, as well as the vault which rested on it, were taken down in process of time out of respect for the martyr, that the altar, elevated in the place of the martyrdom, might be seen from a greater distance. Around and at the height of the aforesaid vault a passage was constructed, from which the *pallia* and curtains might be suspended.

Professor WILLIS says the flat or solid wall mentioned above is to this day preserved, "for this masonry of the fifteenth century which clothes every other part of the transept does not intrude itself here, but is cut off many feet above."

According to GERVASE, the Archbishop had entered the transept chapel while the monks were singing vespers in the cathedral. He was accompanied by three or four of the monks, the faithful GRIM or GRIMES, whose arm was severed, being one of them; but whether a larger number surrounded him is uncertain. Evidently the monks were panic-stricken. But nobody thought at the time of charging them with cowardice or unfaithfulness. Both Celts and Saxons considered the Normans irresistible. If so large a number of monks as inhabited the Canterbury priory had fallen on the four knights who had resolved to remove the king's enemy, they would have conquered the intruders by weight alone. In their first interviews with the Archbishop the knights had exposed themselves to danger, for they left their swords outside the building. Yet not one of the people attached to the cathedral or the priory dared to remove the weapons. From their manner of acting we might suppose the knights had anticipated a different sort of arrangement of the dispute between the Archbishop and the king which would make their swords an encumbrance. If they cared they could easily have slaughtered the whole of the terrified community who had sought safety in nooks and corners of the crypt, behind altars, or wherever darkness was likely to conceal them, and were apparently half dead already with terror. The knights committed no excesses, but limited themselves to the carrying out of the king's desire. The blow received by GRIM was not intended for him. Apparently so much moderation was appreciated. To GERVASE they were "notaries of the devil," which may have signified instruments of HENRY II., and in that age obedience to a chief was accepted as inevitable. In the assessment of ecclesiastical punishments which followed the crime the knights were let off rather lightly if compared with the king's fate, for they were ordered to share in the Crusade, which was generally considered to be a privilege. What is still more remarkable, their statues were set up over the south porch of the cathedral, and three of the figures existed when ERASMUS visited Canterbury. REGINALD FITZURSE, WILLIAM DE TRACY, HUGH DE MOREVILLE and RICHARD BRITO, or LE BRET, were "raging men," but, as good often comes forth from evil, their misdeeds brought riches to Canterbury, in the presence of which, as ERASMUS said, "MIDAS and CRÆSUS would have seemed beggars."

The quarrel between HENRY and his favourite arose out of many causes. TENNYSON does not hesitate to suggest that jealousy on account of the Archbishop's influence over FAIR ROSAMUND was the most influential of all. Many investigators consider the breach was caused by the course adopted by BECKET in dealing with the "Constitutions of Clarendon." If judged by a nineteenth-century standard, the object of the arrangements which bore that title appears right and just. Ecclesiastics, who were unable to inflict more than light punishments, were then able to try criminal cases, and it was the desire of the king that lay judges who could impose sentence of death should try all cases. It is supposed that BECKET, in his opposition, wished to screen wicked clerics from the fate which awaited ordinary offenders against the law. But that is too narrow a conclusion from facts. In an age when four privileged men could scare some hundreds, it was well that privilege could be met by privilege. As MACAULAY says:—"A society sunk in ignorance and ruled by men by physical force, has great reason to rejoice when a class of which the influence is intellectual and moral rises to ascendancy; such a class will doubtless abuse its power, but mental power, even when abused, is still a nobler and better power than that which consists merely in corporeal strength." BECKET did not

seek immunity for clerics alone. Under that class was comprised the bohemianism of the twelfth century. The wandering minstrel who indited a few verses in sarcasm of some noble, the broken-down scholar who manifested his superiority over a courtier, the embryo man of science who was supposed to be a necromancer, or to have an evil eye which affected the great; all, in fact, who could plead their ability to read and write were safe from the intolerance of beings who looked on themselves as belonging to a more exalted race. The clergy might be too lenient as judges, but the Norman magistrate would treat such culprits with scant mercy. Whether BECKET was a Norman or a Saxon cannot be ascertained; but there can be no question that he was accepted as the representative of the downtrodden natives and a martyr to nationality. Patriotism must have had as much to do as religion with the reverence of which he was the object, and which brought English pilgrims from all parts of the island to Canterbury.

How were those pilgrims accommodated? That is a question which is likely to arise in the mind of every reader of CHAUCER'S tales. We know that the majority of the monastic orders exercised hospitality, and from their peculiar constitution as pioneers of agricultural science in wild districts, the Benedictines could hardly be indifferent to the necessities of wayfarers and other pilgrims. In Canterbury guest-chambers and a refectory for strangers undoubtedly existed. This is evident from the ancient drawing which is found in a psalter belonging to Trinity College, Cambridge. It bears no title, but after the investigations of Professor WILLIS there is no doubt it represents the Benedictine monastery of Canterbury. It represents the building at some period between 1109, when Archbishop ANSELM died, and 1174, when the fire described by GERVASE broke out. There was a division between the part assigned to guests and the buildings occupied by monks. The refectory is supposed to be represented by one of the existing residences. The prior's house was so placed and arranged that from it all the principal altars in the cathedral could be observed—a prudent arrangement, for the valuable offerings were enough to excite thieves to commit sacrilege. There was an infirmary, with a chapel, hall and refectory. A part of the walls of the general refectory exists, the kitchen was of large size and octagonal in plan, and there were also a brewhouse, bakehouse and granary in connection with it. There was a circular water-tower or *castellum aquæ* (the remains are known as the baptistery), where water was collected from a reservoir placed about a mile outside the city and distributed by wooden conduits. The dormitory was placed near the cloisters and measured 145 feet by 80 feet. The Benedictines were not as rigorous in adhering to a stereotyped plan as their offshoot, the Cistercians, but everywhere there must have been arrangements for the labours prescribed to the order, viz. agriculture, literature, copying manuscripts, the arts, metal-work, mosaic, history, &c. Canterbury was likely to have been a sort of type of the Benedictine monastery, for to it belonged St. DUNSTAN and LANFRANC, who were restorers of the original rule. In all the other cathedral monasteries the Canterbury system appears to have been followed with one exception, viz. Carlisle.

THE LIGHTING OF SMALL DISTRICTS.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

IT is unfortunately to be noticed that many villages and parishes have no form of street illuminant.

In order that a parish may be lighted it is necessary that the Lighting and Watching Act* of 1833 and its amendments be adopted, as the necessary outlay is otherwise not provided for. This Act makes provisions for the lighting and watching of parishes in England and Wales, and is so worded that it is possible for every village or even a part of a parish to adopt the Act and to participate in the benefits conferred. A clear two-thirds majority of a parish meeting, or a poll if demanded, is necessary for the adoption of this Act.

* According to the Local Government Act (1894) in every rural parish the Parish Meeting has the power of adopting that Act.

When the Act is adopted the form of illuminant generally decided on is oil, owing to the low first cost, as a loan cannot be raised (according to the Local Government Act) without the consent of the County Council, and the expenditure must not exceed a 3*d.* rate. When the parishioners have become somewhat accustomed to the illumination of their streets in this manner their interest in the matter disappears, or they adopt a critical attitude and discover that the light is very poor and that there are frequent failures owing to the elements or the lamp trimmer, and it is very frequently found that the light is abandoned owing to the expense and its unsatisfactory character.

When, however, the streets are again in darkness, and perhaps in a dangerous state, the inhabitants become even more anxious to adopt some form of illuminant which will give greater satisfaction, and the erection of a gas works is suggested and enthusiastically discussed until the question of cost is considered. The initial outlay is very heavy in proportion to the size, and the matter is postponed till an indefinite date, and, in fact, generally until taken in hand by private enterprise and a syndicate formed. In this case private lighting is also anticipated; the benefits of the light are therefore extended, and the inhabitants take an interest in the matter. If private lighting were not considered, the cost of the lighting would be out of all proportion to the light obtained in the streets, and if supplied at a reasonable price per lamp per annum the works would be a complete failure.

In connection with this matter it will be of interest to note a few of the provisions of the Act before mentioned, generally with reference to gas. The pipes must be laid at least 4 feet from any water-pipe, with a view to the prevention of contamination of the water due to leaky pipes. Advertisements must be placed in the local newspapers inviting tenders unless the sum of the contract is less than 20*l.* This applies to plant or to the contract for the lighting of the streets.

For many reasons it is advisable that the supply of an illuminant should be in the hands of the Council. The ratepayers have a direct interest in the matter, and each has an incentive to persuade his friends to adopt the light, and the undertaking is far more likely to be successful, not only because of the benefits to be derived from private lighting, but because the revenue will in many cases cover the cost of the street lighting.

Combinations of neighbouring parishes are permitted by the Act, and herein may be found the means for making the plant a complete success. The application of two parishes to the County Council for a loan is much more likely to be granted, the works will be less expensive proportionally to each, and the cost of supply will be less.

The reasons why a council can supply light at a less cost than a company are that the capital required is less, owing to the absence of company promotion fees and the fact that, most likely, land already owned by them can be utilised, also to the less cost of working, as there are no directors' fees or shareholders' dividends to pay, the interest charged for the loan being much less than that expected by shareholders as dividends. The management expenses are considerably reduced, as the Council is the manager, and, in fact, expenses are lower all round.

A parish council has the power of raising a loan (under the same conditions as a district council), which may be spread over a number of years with the consent of the County Council and Local Government Board.

When small stations are compared, it is found that the cost of erecting a gas plant is considerably in excess of that required for an electric light plant. The reasons for this are that the plant required in a gas works and the buildings are, necessarily, of such a nature as to cover a large area, and cost to erect an amount increasing rapidly in proportion as the sizes diminish. Again, in comparison the cost of working is usually much above that of a large concern, and the reason for this is that, apart from the inherent advantages of a large concern over a smaller one as regards cost of management, &c., the by-products cannot be sold to any advantage. In large works the sale of the coal-tar products, coke, retort, carbon, &c., are as important as the sale of gas, but in the small ones there is practically no market for anything that cannot be sold locally, so one large source of revenue is removed. A gas works cannot take advantage of any local sources of energy, such as water-power, and the cost of the

coal required is often excessive owing to the cost of cartage, and also the gas mains must be buried in the ground.

With regard to electric lighting, it must be borne in mind that this is governed by the Electric Lighting Acts (1882 and 1888). When we consider the position of an electric lighting plant in a rural district, we must remember that the cost of mains may easily be very low, no excavation being necessary if overhead wires are used. This, and the fact that the cost of electric lighting plant is less than that for gas in small sizes, makes the capital outlay smaller. With reference to the cost of working, the prices charged by small gas companies are always far more than the price which could be charged for electricity. The prices of gas from 4*s.* to 7*s.* per 1,000 cubic feet are common, while even with a steam-power station the price for electricity need never exceed the equivalent of 4*s.* per 1,000 cubic feet, and very seldom does.

In cases where water power is easily available, the price of electricity in very small works can easily be as low as 4½*d.* or 5*d.* per unit, equivalent to from 2*s.* 6*d.* to 3*s.* per 1,000 cubic feet of gas. There are very many small country districts where there are disused mills, or other available falls, where plant can be laid down at a reasonable cost.

By the adoption of overhead wiring and the use of water-power (if reliable) there is no doubt that in almost every instance the cost of supply can be less (especially in small towns) than the minimum possible price of gas.

If, added to this, the greater convenience, purity and cleanliness of electric lighting and the facility with which it can be transmitted over considerable distances be taken into account, this form of illuminant should most certainly be adopted in every case for a small district.

The above will apply in every case, as regards distribution of the light, because the overhead mains will cost less than gas-pipes.

With regard to the use of overhead wires, this is permitted in a rural district by the Board of Trade when the undertakers work under a licence or provisional order. The Board of Trade regulations must of course, however, be complied with in any case, but these are not in any way irksome and are really the precautions which any electrical engineer would naturally adopt.

It is usually out of the question to obtain a provisional order, owing to the cost, in the case of a rural district; and therefore the Board of Trade's consent need not be obtained in the matter, provided that their regulations for the protection of the public safety and the wires of the Post Office are complied with; and it may be of interest to give a few extracts relating to overhead wires here.

Extracts from the Board of Trade Regulations.—Every aerial line shall be attached to supports at intervals not exceeding 200 feet where the direction of the line is straight, or 150 feet where the direction is curved, or where the line makes a horizontal angle at the point of support.

Every support of an aerial line shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the line or unequal lengths of span. . . . Every support, if of metal, must be efficiently connected to earth.

Aerial lines shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by uninsulated metal binders.

An aerial line shall not in any part thereof be at a less height from the ground than 18 feet, or where it crosses a street 30 feet, or within 5 feet measured horizontally or 7 feet measured vertically from any building or erection . . . except when brought into a building for the purpose of supply.

Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected. . . . Every portion of any service line which is outside a building, but is within 7 feet from the building, shall be completely enclosed in stout indiarubber tubing.

When an aerial line crosses a street, the angle between the line and the direction of the street shall not be less than 60 deg., and the spans shall be as short as possible.

Where an aerial line crosses or is in proximity to any metallic substance, precautions shall be taken by the undertakers against the possibility of the line coming into contact with the metallic substance, or of the metallic substance coming into contact with the line by breakage or otherwise.

Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

In case of any high-pressure aerial line exceeding one half-mile in total length, means shall be provided whereby the pressure may be discharged from any portion of the line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with the line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the undertakers intend within a reasonable time again to take it into use.

THE ANTIQUITIES OF BURGHCLERE.*

BURGHCLERE, or Borough Clere, has derived its name from being one of the early boroughs of Hampshire. These primitive boroughs were places so named in Saxon time from having a burh or fortification of some kind. Some of these burhs were of Saxon construction, but in places such as this, where an earlier Celtic fortification already existed, the earlier earthwork was often adopted as a defensive work in Saxon time. The burh or borough in this parish was the British camp on Beacon Hill, one of the early camps or castles of refuge, possibly of the prehistoric Iberians, certainly of the later Celtic people, in this part of Hampshire. The camps on Beacon Hill and on Ladle Hill formed together one of the most imposing systems of refuge in the county, defending, as they did, the road between the hills which formed the natural pass from the forest of the Kennet valley to the forest land of North Hampshire in the valley of the Test. There is at the present time a striking difference between these two camps. That on Beacon Hill is included in Burghclere, while that on Ladle Hill forms the northern boundary of the parish of Litchfield. Beacon Hill camp bears the marks of much later work than Ladle Hill camp, which has obviously been neglected since Celtic, and perhaps since neolithic or Iberic time. Those historians or archaeologists who are of opinion that the prehistoric people in this part of England were a sparse, uncivilised race, unacquainted with arts of life and without any organised system of defence, a few painted savages, who roamed in the woods, have in this immediate neighbourhood a striking object lesson. Whence these great earthworks, thrown up with engineering skill, of great extent, following the natural features of the hills, and apparently made strongest where the natural configuration of the hill is weakest? They could not have been made without an enormous expenditure of human labour, and that labour must have required the united efforts of a large body of men. It is extremely improbable that they were constructed by passing bodies of armed men, here to-day and gone to-morrow. They must have been thrown up by people living in this neighbourhood, working at them for many years in times of peace, to make them into castles or camps of refuge for themselves, their families, and cattle when necessity arose in time of war. As flint flakes and other remains of the Stone Age are commonly found on or near the ancient earthworks of the Hampshire hills, it is probable that the earliest defences in these hills were those of the neolithic or Iberian races, and that these were enlarged and strengthened, or reconstructed by the Celts, who followed them. When we consider that Beacon Hill Camp would require more than a thousand defenders to completely man its ramparts, and that no race of people would be at all likely to construct a castle of refuge beyond their power as regards the number of men required for its defence, we may feel sure that there was a large population living in this neighbourhood or within reach of this camp, before the Norman conquest. The great earthwork on Beacon Hill is a survival of that time, and bears on its scarfs some indications of the higher military skill of the Romans, who probably improved its defences, while the camp on the opposite hill, being unnecessary, was neglected. Roman remains have been found on Beacon Hill and in other places in this immediate neighbourhood. The use of the great earthwork thus passed from race to race until the time of the Saxons, to whom it was no doubt left by the Romans in much the same condition as that in which we now see it. It required only occasional repairs, such as were provided for by the allodial tenure of land in Anglo-Saxon time, and the allodial tax known as burh-bote for repairing local fortifications. This tax or tenure by the service of repairing the local fortifications when considered in

reference to Burghclere—a place which has derived its very name from this custom or tenure—marks it as one of the early boroughs of Hampshire, and among which none have retained the early Saxon name to the present time in so marked a way.

There can be no doubt that Burghclere is the Clere mentioned in Domesday Book as having among its inhabitants twenty-four coliberti, in addition to villeins, borderers and slaves. That these coliberti, whose name showed that they possessed borough privileges, were free men as compared with the other people on the manor is certain, and that their predecessors held their privileges for the obligation of repairing the local defences is very probable. Coliberti, similar to those of Burghclere, are mentioned in Domesday Book as living in Hampshire only in those places which had similar local defences and similar burh or primitive borough organisations. Some of the farm lands of Burghclere must be the same old lands which its Saxon freemen, or coliberti, held more than a thousand years ago. Burghclere was a good example of an early borough community. The primitive idea of a borough appears from the examples recorded or existing in Hampshire to have been a place where the inhabitants, or the most privileged of them, possessed a burh or place of refuge, and formed a community for its defence. As regards Burghclere itself, its coliberti were probably relieved in the later Saxon time from any onerous duty in this respect, for in the charter of King Edward to Bishop Frithstan, dated A.D. 909, it is stated that the Bishop's land at Clere shall henceforth be free from the three obligations of thane service, of which the repair of the local fortifications was one. Some of these primitive boroughs never grew into towns, as towns were understood in the Middle Ages, but remained stationary, or gradually dwindled in population, so that at the present time it is difficult to recognise such places as Burghclere, Bramley, Kings Somborne, Barton Stacey, Wherwell, Meonstoke, Wallop and Broughton as some of the earliest boroughs in Hampshire. These, however, were among the early Saxon boroughs of this county, and their origin as boroughs was derived from their burhs or local defences. Boroughs in England existed before cities. The "borough" is the older name, and was the older organised community. Burghclere can claim, therefore, to have had an organised existence as far back as that other primitive borough which afterwards became the city of Winchester.

One of the lesser Roman ways of Hampshire was that which connected Winchester (Venta Belgarum) with Speen. It must have followed much the same line as the present road, passing Bullington Camp, where Roman remains have been found, and Whitchurch, where sites of buildings and other traces of the Romans have of late been discovered, and so on through Burghclere. The old sunken road, now disused, near Whitway may be part of its track. Roman urns have been found a little distance north of Burghclere old church. The street names of Burghclere and Highclere, such as West Street and Highclere Street, are probably significant of their position in reference to the Roman road or street which is mentioned in a charter of Edward the Elder, dated A.D. 909 or 910. Saxon charters relating to Burghclere and Highclere exist, and the "two parishes" of Burghclere and Highclere, in which the Bishop of Winchester's (Alfsige's) land was situated, are mentioned in King Edward's charter, A.D. 910, and a parish implies a church. The church of Burghclere is mentioned in Domesday Book, and although the present church for the most part is of somewhat later date, yet it is not improbable that the building thus referred to stood on the same site, and that some of the materials at least of the Saxon building were used in the construction of the oldest part of the existing church. There is one circumstance which points to Bishop Walkelin as one of the probable builders or restorers of this church, which has a Norman doorway on its south side. It is partly constructed of Binstead stone, which could only have come from the Isle of Wight. William the Conqueror gave his kinsman, Bishop Walkelin, permission to quarry the stone at Quarr, I.W., for the Norman cathedral he built at Winchester, and some may have been sent to Burghclere at that time to be used in a church on the bishop's manor. It is certainly a long way to bring stone from the Isle of Wight to Burghclere, but Winchester is only about eighteen miles distant, and if, as is not improbable, after the cathedral was built, there was Quarr stone still left at Winchester, it is not unreasonable to conjecture that it may have been used for the doorways and other parts of a church on a manor owned by the bishop himself, to whom the stone had been granted. In any case some of the stone was there, in a church of the bishop's own, and we know that he had permission to dig it.

To the student of archaeology, groping his way in the dark and endeavouring by modern research to learn more of the dim past, any gleam of light which may possibly guide him is welcome. Such a gleam in reference to Burghclere appears to be afforded by the dedication of the church—All Hallows, or All Saints. Kingsclere Church is dedicated to St. Mary, the patron saint of Rouen Cathedral, which owned the manor. Highclere Church, on the estate of the Norman bishops, is appropriately dedicated to St. Michael, the patron saint of

* A paper read by Mr. T. W. Shore on the occasion of the visit of the Hampshire Field Club to Burghclere.

Normandy, and the saint to whom the religious houses on Mont St. Michel and St. Michael's Mount in Cornwall were dedicated—the saint of altitudes, appropriately chosen for Highclere. The dedication of Burghclere Church to All Saints appeared to have been chosen in early Saxon time on account of its special significance to the parish and of its catholicity. The Saxons who settled there found on all sides of them the remains of their more ancient predecessors, their roads, their great earthworks, and their great funeral mounds. The beginning of November, or All Hallows-tide, was the time when the Celtic races of Europe commemorated their ancestors, as indeed they still do, when all fires were extinguished, and the living conversed with the spirits of the dead. Such a custom could not fail to have been transmitted from race to race in this neighbourhood. The boundaries of this parish include both Beacon Hill and the Seven Barrows. Near it occur such partly mythological Celtic names as Sidmonton, Sidon and Sidley Wood, which, on the authority of the Professor of Celtic in the University of Oxford, must be ascribed to Sid, the fairy mounds. The neighbourhood abounds in suggestive memorials of the remote past, and he thought it probable that, after the Saxon conversion and in accordance with the instructions of Pope Gregory, Pagan festivals should be adapted to Christian uses, Burghclere Church became appropriately dedicated to All Hallows, whose vigil is the still wider commemorative festival of All Souls, a commemoration wide enough to include even the old Pagan Celts, who cremated their dead and reared the barrows over their ashes, or our own Anglo-Saxon forefathers, of whose mythology we are reminded by the names of the days of our week.

The rectory of Burghclere is one of much interest from its ancient Saxon endowment and its later historical and archaeological associations. It was a manor in itself. Its endowment is mentioned in Domesday Book, where it is stated that a cleric, a priest, held of the bishop one hide of land, together with a church, and that he had one ploughland with a borderer and two serfs, who worked on the priest's land or manor, and also an acre of meadow, which, together, in the money of that time, is stated to be worth forty shillings annually. Two hundred years later, in 1291, we come upon another entry relating to the rectory in the taxation of Pope Nicholas, which states that the church of Burghclere, with its chapel, was worth 26*l.* 13*s.* 4*d.*, while that of Highclere was worth 8*l.* The chapel was that which afterwards became the church of Newtown, a new township or parish so named in the thirteenth century, in the northern part of the parish. Fifty years later we again come across an entry relating to Burghclere church and its ancient endowment in the "Inquisitiones Nonarum," dated about 1340. The parish of Burghclere, with the exception of its tithing of Earlstone, is in the old Saxon hundred of Evingar, which is recorded in Domesday Book, and of which the prior of St. Swithun's was the lord. The Manor of Earlstone was held by a different tenure, and was included within the hundred of Kingsclere. Its name was probably derived from the earl or alderman who held the manor in early Saxon time. The alderman was the highest dignity next to the king, and their later successors in the dignity became known as earls.

There are some interesting entries relating to Burghclere in the Papal registers preserved in Rome, several volumes of which, in the form of a calendar, have lately been published by the English Records Commission. The earliest of these entries was dated 18 Kal. Septem. 1297, when a Faculty was granted by the Pope to the Bishop of Winchester empowering him to give the church of Bourchere (Burghclere), void by the death at Rome of Master William de Wellingue, to any fit person. By this it appears that the rector, Master de Wellingue, went to Rome probably on some business or suit at the Papal Court, a long and laborious journey, but a common one, and that he died while prosecuting his suit there, a not uncommon circumstance in the Middle Ages. Other entries, as well as some from the Patent Rolls, were referred to, and some interesting petitions to the Pope relating to Burghclere were read in detail. Several of the Mediæval rectors of Burghclere occupied prominent places in diocesan history. The old rectory house contains some remains of the site of these early rectors. Part of the roof of the dining hall still remains, and several walls which were part of the Mediæval building, and the Club would have an opportunity of seeing these by the kindness of Mr. Holding. It is interesting to note that the walls are built of local stone of the geological age of the upper greensand, which comes to the surface in the Kingsclere inlier. Burghclere formerly had extensive common lands, which extended, like those of Kingsclere and Sidmonton, to the Berkshire boundary. Burghclere and Highclere Commons being under the same lordship, were enclosed by the same Act of Parliament, passed in 1783. The common land of Earlstone, a separate manor, was enclosed by an Act of its own, a copy of which is in the Cope collection of Hampshire books and pamphlets in the Hartley Library at Southampton. A curious

survival in this parish until recent time was that of the old chace-privileges of the bishops of Winchester. The bishop's chace gave him the right of hunting not only in his park at Highclere, but over all the outside lands within the limits of the Chace—the manors of Highclere, including Burghclere and Etchingswell—and this right, which had descended with Highclere to the Earl of Carnarvon, having been disputed about fifty years ago, a lawsuit followed, which was decided in the earl's favour.

ENGLISH SEALS.

THE "authenticum" and "secretum" of the Frankish sovereigns were the primitive types of the Great Seal and Privy Seal introduced into England after the Conquest. It seems to be possible that seals may have been occasionally employed in Saxon times, as that people must have been cognisant of their use in France; but it could not be asserted, on the authority of one or two supposed instances, that the practice was at all general. The Saxon charters to which were pendant the broad seals of Saxon kings mentioned in some of the letters of the commissioners of Henry VIII. for the suppression of the religious houses were probably fabrications. Pendant seals, or "bullæ" as they were originally named, were of metal—gold, silver or lead; they were struck from dies in the same manner as coins, and in the earliest periods had no reverses. Thus in their nature they were more analogous to coins or medals than to seals in the present acceptation of the term. The use of metal bullæ for the authentication of very solemn and important documents prevailed among secular princes from the times of the successors of Constantine to the days of our Henry VIII. Two remarkable examples of golden bullæ are still preserved in the chapter-house at Westminster; one of the thirteenth century, pendant to the Dower Charter of Eleanor of Castile, consort of Edward I.; the other, which has been attributed to Benvenuto Cellini, is attached to the treaty of peace between Henry VIII. and Francis I. of France. The antiquity of papal bullæ has been much disputed by antiquaries; their use continued to the present time, and may probably be referred to as early a period as the tenth century. The Doges of Venice continued to use pendant metal bullæ until the suppression of that republic. The inconvenience attending the production of metal impressions must have naturally suggested the application of the die to a more plastic material, hence the employment of wax. In this country, after the Conquest, the matrices of seals were of metal—silver, brass or lead; the latter, from the facility of working it, was most commonly used in the twelfth and thirteenth centuries, and more especially by individuals of the middle class. The wax employed was of various colours and varied composition. In the earliest impressions of English seals, it is generally, though not invariably, white, and from some defect in its preparation is usually in a very friable and decayed state. Red and green then became the prevailing colours; and in the sixteenth and seventeenth centuries white was again generally used, particularly for the Great Seal and the seals of the several courts of law. During the Middle Ages antique intaglios were used as seals, particularly as secreta or privy seals. They were generally surrounded by Mediæval legends, which were often grotesquely inapplicable to the subject of the gems. As regarded the shape of Mediæval seals, the principal forms were circular or an acute oval shape (*vesica piscis*). Ecclesiastical seals were generally, though not always, of the latter form. There were, of course, numerous variations from these shapes. In the twelfth and thirteenth centuries seals were, for the most part, oval in outline. In the fourteenth and fifteenth centuries circular forms were generally used. Viewing seals as applied to documents, it was to be observed that it is perhaps from the early part of the thirteenth century that we must date the practice of impressing the seal upon the document itself instead of suspending it therefrom by silken threads or a slip of parchment. Strictly speaking the pendant seal belonged to documents intended to convey general notifications, to letters unclosed or patent, yet many anomalies are to be noticed in its use. Documents of a private nature were folded, and the seal so impressed on the folds that the contents could not be attained without breaking the impression; and it may be remarked that a curious practice grew up during the fifteenth century of surrounding seals so impressed by a twisted band of straw, doubtless with a view to their better preservation. This fashion, very prevalent during the time of Henry V., continued until the sixteenth century.

A Marble Tablet to the memory of the late Archbishop Benson has been erected in the Garrison Church at Canterbury, the dedication of which building was one of the last public acts of the kind performed by the Primate prior to his sudden death at Hawarden. Dean Farrar, in unveiling the memorial, stated that this was the first memorial ever erected by British soldiers to an Archbishop of Canterbury.

NOTES AND COMMENTS.

THE Public Health Acts would lose much of their authority if the clauses could be construed into an injunction to employ a specialty of any kind. Whatever may be its shortcomings, the British Legislature does not consider itself to be under an obligation to promote private interests, and that spirit inspires other Acts besides those for insuring public health. As a rule, corporations and local authorities generally respect the intention of Parliament, but through oversights it sometimes happens that the influence of a local authority appears to be partially exercised. Such a case has occurred at Widnes. In February 1895 the health committee of the Corporation adopted the following resolution:—"That in all future cases of nuisances requiring the reconstruction of privies and ash-pits the local authority of this borough do, as far as practicable, order that such privies and ash-pits be converted into the waste water-closet system, or into such other water-closet system as the local authority may from time to time approve, and that the highway committee be requested to take such steps for the adoption of the first-named system generally throughout the borough." It is likely that the resolution applied to a whole species of closet rather than to one particular invention and that a householder could select any waste water-closet which appeared to be sufficient. Anyhow, an owner of sixteen houses in one road neglected to obey a notice requiring him to put in waste water-closets. The Corporation therefore carried out the work and claimed the amount paid from the owner. On the application of the owner a case was stated by the justices which came before Mr. Justice LAWRENCE and Mr. Justice RIDLEY on Saturday last. The whole question turned on the meaning of the resolution of February 1895. Mr. Justice LAWRENCE said the local authority could not prescribe the use of a particular kind of closet—each case must be inquired into and the requirements of individual houses considered. The resolution was therefore invalid. Mr. Justice RIDLEY said that, although uniformity might be desirable in such cases, Parliament had not declared in favour of the principle. The appeal of the owner was therefore allowed. All that the public health demands is a "sufficient" water-closet. The local authority is a judge of the sufficiency, but cannot urge the adoption of any special kind as possessing the quality.

It is improbable that opinion will ever be unanimous about the worth of RABELAIS. All the sayings and doings of GARGANTUA and PANTAGRUEL may have an occult meaning, which interpreters can make out as signs of exquisite fancy, but the world would not be much poorer if the book had been kept in a manuscript form. RABELAIS was born in Chinon, which is in Touraine, but his life was spent elsewhere. The Touranians continue to be proud of him, and from him they have derived some of their peculiar humour. But they have ceased to remember where in Chinon he was born. Owing to the patient researches of M. HENRI GRIMAUD the site of the apothecary's or inn-keeper's house, *i.e.* the elder RABELAIS', has been determined. It was on the ground where No. 15 now stands in the Rue de la Lamproie, and was removed in the last century. In order that doubts may no longer arise, a tablet in black marble has been placed on the façade with the following inscription, "Ici s'élevait au XVI^e siècle la Maison de RABELAIS." As there was a farm belonging to the inn outside Chinon, there was a tradition that it was the birthplace of the humorist, but now that a tablet exists we suppose the Rue de la Lamproie will have a monopoly of the honour.

M. EDOUARD DETAILLE has been raised to the dignity of a commander of the Legion of Honour. The promotion was well deserved, for the painter is the most successful of all who treat military scenes. It may be said of him also that he is the only foreigner who is competent to represent the British soldier. Life-Guardsmen, Highlanders, or the ordinary rank and file linesmen, appear in his drawings with a truth to nature which is remarkable. M. DETAILLE appears more like a member of the Guards' Club, Pall Mall, than a French artist. At the present time he deserves

any honour his countrymen can bestow, for, owing mainly to his exertions, influence, and knowledge, the new museum which is devoted to the history of the French army in the Invalides is a success. For the museum M. DETAILLE has despoiled his most interesting atelier of many of his treasures. Moreover, he is a favourite at the Russian court owing to the excellence of his drawings of Russian soldiers. As becomes a pupil of MEISSONIER, there is much precision in his drawings and paintings, but they are never suggestive of laborious attention to detail or the sacrifice to it of finer qualities. Among other works of the painter which were reproduced in *The Architect* is a design for a frieze which was specially prepared for us.

THE juries of the Brussels International Exhibition have in several cases arrived at their decisions. In the Fine Arts section first-class medals have been awarded for painting to Mr. DICKSEE, R.A., Mr. HERKOMER, R.A., Mr. HOOK, R.A., Mr. GREGORY, A.R.A., Sir J. D. LINTON, Mr. WATERHOUSE, R.A., Mr. SEYMOUR LUCAS, A.R.A. and Mr. SARGENT, R.A. The medal for sculpture is obtained by Mr. ONSLOW FORD, R.A. Second-class medals for painting have been awarded to Mr. SOLOMON, A.R.A., Mr. LAVERY, Mr. MURRAY, A.R.A., Mr. NORTH, A.R.A., Mr. ORCHARDSON, R.A., Mr. AUMONIER, Mr. C. GREEN, Mrs. ALLINGHAM, Mr. OULESS, R.A., and Mr. CLAUSEN, A.R.A.; for sculpture to Mr. FRAMPTON, A.R.A., and Mr. DRURY; for engraving to Mr. CAMERON; and for architecture to Mr. PEARSON, R.A. The five gold medals in the Fine Arts section have been voted to Mr. ALMA-TADEMA, R.A., England; MM. DETAILLE and FLAMENG, France; and MM. COURTENS and LAMBEAUX, Belgium.

CATHEDRAL SERIES.—CANTERBURY: THE MARTYRDOM.

TASMAN, TUFNELL PARK, N.

THIS house is now in course of erection in the Anson Road, Tufnell Park, from the designs of the estate architects, Messrs. TRUEFITT & WATSON, members of the Royal Institute of British Architects, of 5 Bloomsbury Square, W.C.

The main fronts are to be faced with red heather bricks with stone dressings. The roof will be covered with Bangor slates, and the woodwork painted white.

CRICKET PAVILION, BERKS COUNTY CRICKET CLUB, READING.

THIS pavilion has just been erected on a site recently acquired by the B.C.C.C. committee, and which formed part of the Elm Park Estate, Reading. It will be opened next week by H.R.H. Prince CHRISTIAN. The elevations are carried out in half timber, and filled in with red brickwork and white pointing. The roofs and *flèche* are covered with strawberry-tinted tiles.

The building consists of luncheon-room 40 feet by 19 feet, with open timber roof about 17 feet high to plate; a committee-room and two dressing-rooms, one for the use of members and the other for visitors, each opening into the luncheon-room, to which is attached a refreshment bar. A room for professionals is also provided. Bath-rooms, latrines, lavatories, &c., are attached to each dressing-room, also an annexe for the use of professionals.

On the first floor is the scorers' and press-room with balcony. Adjoining is a large store-room for bats, &c. for the use of the ground man.

The balcony is reached by outside staircases on either side of the building. The front enclosure, 100 feet in length, is raised in three terraces, with a portion divided off for the accommodation of professionals. The work has been carried out by G. S. LEWIS & BRO., builders, from the designs and under the superintendence of Mr. GEO. W. WEBB, F.R.I.B.A., Market Place Chambers, Reading.

TECHNICAL EDUCATION IN ARCHITECTURE AND THE BUILDING TRADES.*

IN giving this title to the short paper which follows I do so to explain its scope in current phrase. For myself, however, I must explain that I acknowledge no distinction between architecture and building. Architecture is the resultant of the association of the several building trades—it is the centre of gravity, as it were, of the crafts in combination.

While it is generally admitted that there is now no common speech and tradition in building matters, no current style of architecture; there has been much attempt to extol this architecture as something quite superior to mere common building. Fergusson, for instance, in trying to make out such a distinction, says in effect that building is mere heaping of material together, while architecture is building done with thought and arrangement. He thus gives the title of building to a wholly supposititious product which has never had any concrete existence, so that he may give the title of architecture to building as we know it historically.

It suffices to say that the building product of antiquity is never so treated. The history of the architecture of Greece is what we know of the buildings of Greece—religious, military, domestic; the architecture of the Middle Ages is the masonry and carpentry, the smithing, plumbing, and so on, brought together in the wonderful works of that age. It follows, therefore, that the endeavour of the historians of art is to get at the typical and spontaneous in the art of the past so as to reconstruct the ages by all the monuments they have left behind. Modern English architecture is truly the whole product of the current customs of building in England. The architecture of London is the mass of building from Bow to Putney and from Hoxton to New Cross; and it is in the multitude of ordinary and characteristic buildings rather than in the few and exceptional ones that what is typical of this architecture will be found. The question of education in architecture is therefore not a question of nice scholarship which might affect the more costly buildings, half-a-dozen restaurants, clubs and insurance offices; it is the question of influencing the building of mean streets and the ordinary dwellings and meeting places of men. It is not merely an academical question, but one of enormous practical importance to humanity and civilisation.

The Meaning of Style.

An explanation of the more apparent causes which led to the admitted breakdown of tradition in architecture—that is, building—in these modern days is part of a long story. Before glancing at it, it will be well to gain a clear idea of what this thing "style" has been in the past when art was, as we say, living. At such periods architecture, as we can now see, was a natural development, the outcome of the experimental building carried forward by masons and carpenters. We see the needs and aspirations of society, the materials used by the builders, and all the other conditions of climate, circumstance and thought so directly influencing their manner of building that it became a common and organic growth. This organic principle of building, the style, was a remarkable essence, a principle of growth born of the contact of mind, senses and emotions with outer conditions; this style was not an accident, not a thing to be willed or altered, it was in the nature of things spontaneous, communal, national, racial. A building was a natural product, another kind of tree, as it were, growing on the earth's surface, answering to every condition of soil and climate and responding to every breeze of thought.

Literature is but the written word, architecture is the builded word; the writer and the builder are alike nothing except so far as they crystallise some of the thought stuff behind phenomena—the ideas waiting to be born. And further, a true style can only answer to one moment in the world's history; we may speak of Hellenic or Byzantine and of the thirteenth and fourteenth century styles, but really style changed from day to day. Any mere invention, if it were possible, of new shapes, any intentional originality, would be as trivial as our copying of the styles of the past. Of course, I must be understood to speak of expressional forms, not of useful inventions.

Our modern relation to facts on the side of architectural thought is, of course, exactly represented by our current building speech. We are revealed to ourselves in the corrugated iron shed, the mean meeting-house, the restored cathedral, the sham Gothic church, the sham Renaissance town-hall, the dull workhouse, silly villa, and the general vulgarity of the streets.

All this is ourselves built large, and yet I hope that we are not so bad as we look, for we are the victims of our historic position, and if we find ourselves in a *cul-de-sac* we didn't put ourselves there. Still it is a melancholy reflection that all this time there would have been a true style of building proper to this moment alone in the world's history, if we could only have been in connection with the great governing principles of

practical building, a vital stream, instead of being choked by the scum of an outspent eddy of scholasticism.

I am going to become more practical instantly, but what becomes of the architecture never built—the architecture of 1897?

Our Historic Position.

At the beginning of the sixteenth century a vast revolution occurred all over Western Europe. The Church broke in two, traditional customs were largely replaced by statutes imitated from Roman law, the free towns were overawed and the national folk architecture withered up before a fashion for imitating Roman building seized on with avidity by all the Courts in Europe. Reformation, revolution, Renaissance, were but complementary phases in the fields of religion, politics and art of one great movement by which the guilds were dissolved, the ideal of the towns uprooted and the craftsmen who governed them taught their place. The guilds of the workmen had been inextricably bound up with religious brotherhoods and with the corporations of the towns (the municipalities or communes were, indeed, based on the guilds), so all were struck at together.

The revival of learning, as it is called, worked in perfectly with the great wave of reaction and absolutism. Roman law was ransacked for pretexts, and a scholarship of Roman art became a lever to thrust out of the way the customs of the crafts as held by the guilds. At this time a set of drawing-master designers, commercial travellers in art, came from Italy and hung about the courts of France, Germany and England, and displaced the old master masons and carpenters who held the living traditions of building art. These Italian designers were for the most part painters rather than masons, and from this time the architect became a painter or drawing-master of buildings rather than a graduate of the shops.

As the old architecture of the people was to be broken down arguments were easy to find. One of the most potent and convincing of these arguments is that which is set out by one of the earliest and ablest of the drawing-master designers of France, Philibert de l'Orme, thus:—Roman architecture was antique; Solomon's temple was built in antiquity, therefore Solomon's temple was built according to Roman architecture; but the plans for Solomon's temple were drawn in heaven, therefore Roman architecture was divine and revealed, and the ways of building followed by the Mediæval masons were of the nature of heresy. It was necessary, according to De l'Orme, to return to the "vray" architecture in its purity.

Building from this time ceased to be experimental workmanship, tradition behind and reason in front; it became an essay in "vray" architecture, and scholars in classical antiquities passed themselves off as "architects," which they could the more easily do as the old experts in building were employed to do the work while the scholars provided the pretty patterns, not according to the customs of the craft any longer, but such as might tickle the fancies of Italianised employers.

But it is easy to see that this theory could not last. Scholarship feeding on a limited field soon exhausted itself. Nothing remained to the scholarship theory of architecture when this exhaustion had become apparent but flatly to reverse the argument, and this Pugin did. Pugin arose with beautiful enthusiasm to prophesy that the old despised way of building practised in the Middle Ages which had come to be called "Gothic" or barbarous was the true Christian style after all. Then the scholarship engine was set going once more full speed astern.

This cry, in turn, exhausted itself in some sixty or seventy years; we can see, indeed, that this was in the nature of necessity. This second school of copyists were not nearly so unanimous as the former, nor were the students so self-convinced, yet it is to be noticed that both these revivals (so called) were entered on with a certain belief and fervour—the revival of antique, true or revealed architecture, and the revival of true, Christian or pointed architecture. The first entirely succeeded in suppressing "Gothic" architecture; the second only half succeeded in establishing sham Gothic architecture.

So much for the immediate past; what of to-day? These two enthusiasms having been worked through, scholarship is not equal to another act of faith, and has fallen into architectural scepticism. We don't believe in any architecture being "vray" now. So far as scholarship of design goes, there is now no attempt to work in concert except by the professors of church restoration, who follow Essex and Wyatt in rebuilding the cathedrals to taste and with despatch. This tail of the Gothic revival cannot, however, last for more than a few years. When all the real Gothic has been altered into sham Gothic, that enthusiasm also will have evaporated.

All theories of what has been called "architectural design" have entirely broken down under examination, and it has become apparent that the truer the style is, the closer is its relation to its time and environment. It has become apparent that there is no absolute architecture, but that true style and rational building can only be the outcome of the conditions of the moment in the wise satisfaction of true needs, and by the interaction of handiwork and the materials with which it deals.

* A paper read by Mr. W. R. Lethaby before the International Congress on Technical Education.

While we have been finding out this, it has become as clearly evident that any lingering remnants of the old system of workmanship preserved traditionally by the workmen are disappearing. Just as we have realised that the very basis and main substance of architecture are beautifully built walls of carefully selected materials, timber framed in a workmanlike way, deftly laid plaster, columns proportioned to material, windows and doors shaped for service and so on, and not certain patterns arbitrarily selected by a professor of design, it has become evident to us that the body of workers' skill which the earlier masters of "design" like Wren had to deal with has been continuously decaying and disappearing since the destruction of the guilds. For be it remembered that some of the methods of the guilds survived for long their official destruction. At the beginning of this century the theory of the crafts being based on due apprenticeship was still maintained. And in country towns some who called themselves masons and architects were still to be found.

We designers on the one side have lost faith in scholarship in design; on the other hand the workers are untaught, and therefore unintelligent and uninitiated.

The Guilds.

To look back again to the Middle Ages. The masons and carpenters' guilds were faculties or colleges of education in those arts, and every town was, so to say, a craft university. The folk of the Middle Ages were not so ignorant as to look on dead languages, history and statistics as the only forms of learning. Masonry, carpentry, smithing, plumbing, were media for the exercise of intelligence and aspiration. It has been well pointed out by a recent historian of the universities that they are but surviving examples of the associations of the Middle Ages—scholars' guilds.

Corporations of masons, carpenters and the like, were established in the towns for the ruling of production and the teaching of the craft. Each craft aspired to have a college hall; and a city like London was full, first of the buildings of the religious brotherhoods—the churches; then of the halls of corporations or lay brotherhoods. Guildhall was, as it were, the secular cathedral on which the smaller company halls depended, like parish churches, of trade and craft. We are usually told that "feudalism" was the social principle of the Middle Ages, as if there had been a "social contract." The truth is, society in the Middle Ages formed itself into groups, mainly in accordance with the callings of its members. The association or group, not the individual, was really the unity of society and basis of competition.

The guild, which regulated all the customs of the trade, guaranteed the relations of the apprentice and the master craftsman with whom he was placed—master, be it noticed, not in the sense of employer, but in the sense of graduate of his craft college and wearing its robes. The boy was really apprenticed to the craft as a whole and ultimately to the city, whose freedom he engaged to take up. The boy apprenticed to a mason mixed mortar, tidied the shop, and generally learnt his craft by assisting an expert during a seven-years' course. Each master might only take one or two apprentices at a time, for they learnt by working with him. At a certain stage the apprentice became a companion or bachelor of his art, and later by producing a master-work, the thesis of his craft, he was admitted a master—one of the governing body of his college, and only thus was he permitted to become an employer of labour. Then as a citizen the dignities of the city were open to him and the great things of his art. He might become the master in building some abbey or cathedral or as king's mason, one of the royal household, and the acknowledged great artist of his time in what was then called mason-craft. The buildings of the Middle Ages are indeed wonderful, but is it so wonderful after all that they were produced when the building trades were so organised? Our ideals and system are as perfectly reflected in our modern architecture of London, where a vast mass of common building, which I will not attempt to describe, is diversified here and there by a careful design done out of an architect's head after study of the real mason's art of the past, and built by farming out to a financial agent called a contractor, by gangs of men who have no say in the matter, and who for the most part have "picked up" their trade.

Some argument has been spent on the question as to whether the modern trade unions represent the ancient guilds. The question in one respect is as nice a one as that of apostolic succession in the English Church. In a broad sense, however, there is not the least doubt that guilds and unions are alike forms of those associations of the workers which are known to have existed far back in Greece, were highly systematised through the Roman and Byzantine eras, won their highest positions with the assumption of the government of the free towns by the merchants and craftsmen in the Middle Ages; and crushed and disinherited in England under Henry VIII., reappeared in the various forms of benefit clubs, wages unions, and the trivialities of freemasonry. What we all by the meaningless term Gothic architecture was the

ordinary current work sanctioned by the guild. From such considerations I have reached the conclusion that the building system of any time and country has always represented the state and activities of the guilds or unions. Now, as the organisation of scholarship is the affair of scholars, and medicine the business of doctors, only masons and carpenters can organise and develop the arts of masonry and carpentry. If ever a living style of architecture can again be made economically possible it is by the unions of the several crafts assuming guild functions, seeing to the education of its learners, setting a standard of quality in production—in a word, assuming the entire responsibility for the whole conduct of their crafts—and nothing effectual can be done without them. If the unions, stirring themselves in this way, can vitalise the building crafts, we shall get a building art once more, otherwise we shan't. The real question before the unions is not one of a halfpenny an hour more or less in wages, but the architecture of their country. They are far from realising this responsibility—we are far from having a reasonable and living style of building.

Of Schools.

The members of unions or guilds must themselves consider the matter of education. This work done for them from without would be of comparatively little good. The education itself would be of less value than the interest and goodwill which would vitalise any craft which took up its own education. Moreover, there is likely to be large waste in any system of specialised craft education organised from without. Such a system often eats up the substance; by an artificial preoccupation with the fringes of a subject, and in too carefully considering all the avenues of approach the thing itself at the centre may never be reached. Professional education generally is prone to run to grammar as in the English system of teaching languages. Literary organisers of education have a great dislike to empirical methods; but art itself is empirical, and our literary friends must not deceive themselves by their own phrases. If, as we are told, we are to be governed by experts, the things of art and craft must be organised by expert artists and craftsmen. Indeed, the modern literary view of education—that the chief end of man is to count statistics and read newspapers—must be broken with in approaching this question of craft education, for I believe we shall not get very far till we recognise that a literary education is only one of a dozen avenues leading to true but dissimilar culture. Craft excellence must once more be made an object of ambition, through which the craftsman as such may reach to some of the world's rewards, such as they are. The only reward obtainable in a craft must not be the getting out of it.

It should be a warning to craftsmen that the downfall of the crafts, brought about by the conspiracy of the Renaissance, has been confirmed in the name of science by the gentlemen who, undertaking research into the laws of production and distribution, considered only quantity, and never once thought about the quality of products. May I say here, in brackets, that the position the State, the public, democracy, or whatever we like to call it, occupies as employer of labour is a very important question indeed? At present public works tend to a base mechanism varnished over with what is thought to be ornamentation. What is the good of endeavouring to teach art if we would have none of it if it were produced?

But to return. School learning, however practical, can only form a small portion of the true education of the true craftsman. The organised crafts must further find a way by which the essentials of apprenticeship shall still be obtainable in the shops and on the works. The essential of apprenticeship is the association of a learner and craftmaster in real production, under the sanction of the guild; this also must ultimately be the affair of the unions. If we are to make architecture an experimental art once more the foundation of the whole structure will have to be a number of schools in the several building crafts. In a school of masonry for instance there would be a museum of stones and a collection of tools. Strains and crushing weights would be investigated experimentally, and the equilibrium of arches and vaults studied. Problems of setting-out and practice in actual cutting should go hand in hand. Methods now gone out of use such as axing would be tried over again. Such a school in the hands of expert masons willing to consider methods new and old on their merits, would, I think, soon alter our current procedure. In a few years I should expect to see the present method of rasping the external face of masonry all over with a drag and leaving it to the weather with the pores well laid open, given up in favour of the traditional plan of finishing the face with a sharp-cutting axe and coating it at once with whitewash, which in old times was used as a thin preservative coat of plaster. I should expect the trade taking cognisance of these tests of material and research as to methods to make known the results, so that a body of sound rules in masonry might be made available. At present masons whisper that certain large London works specified to be built of Portland stone are really often executed in Ancaster, or even Bath stone.

The old guilds appointed "viewers," "searchers," or "wardens" to keep their eyes on this sort of thing, which they would not allow for the honour and true welfare of masonry. All this is the affair of the craft, and we must charge on the union the responsibility of seeing to it.

I suppose similar schools to exist for carpentry, plastering, plumbing, all of them nearly lost arts in any high sense, design in every case being approached as an outcome of positive conditions, not as an arbitrary pattern devised by hashing up the forms truly evolved in the past by experimental workers.

Architecture is, I have said, the combination of these crafts to special ends. The architect of the past (best represented by the building foreman of the present) was a mason or carpenter, and I am convinced that ultimately the great crafts should largely reabsorb the architect. In the meantime, however, although the path must be opened out by which the able practical mason and carpenter may become directors of building, it is necessary to educate a class who are specially brought up to direct crafts they do not practise, so that they may direct them as little capriciously as may be. The youth intended for an architect should in every case pass through the elementary stages of the masonry and carpentry schools along with the masons and carpenters, and he should have the run of all the other craft schools under certain conditions. He should, moreover, in a special school of building consider the crafts in combination, and the conditions and traditions of the several types of arrangement suitable for different classes of buildings. As a return of courtesy and service this school of architecture should be open to the craftsmen who wished to know something of building as a whole. The architect's special work is to be an expert in arranging and combining. The quality and details of the masonry are necessarily mason's matters; the curls and twists of the ironwork are the blacksmith's business; plumbing, sanitary and ornamental, is plumber's work; it is a ruinous policy, which instead of throwing on the workers the responsibility in their several trades, stirs up their instinct to get the better of clerks of works and architects. The architect's essential function is not to guarantee the quality of materials and workmanship he does not fully understand; it is not to design ornament out of his head so that materials which he has never wrought with his hands may be tortured into a semblance of his intention by mechanical workmen; his true function is to arrange and contrive highly specialised buildings, to act as an intelligence department for the several crafts, and as one having a knowledge of building as a whole to advise his employers.

At the present time building should be plain, straightforward, sound, and, as far as may be, reasonable; mere plainness and even baldness do not insult us like heartless bedizenment, or the assumption of the trappings of antiquity.

Mr. Powell said the writer suggested that the unions were to take up the work of teaching building and architecture, he should like to know how he proposed to vitalise the unions and get them to take up this work. So far as he knew they were not eager to move in that direction at the present time.

Mr. Lethaby, in reply, said that was a large question, and approached the subject from above; his paper might be taken as intended to stir up the unions from beneath. It was not for him to show how everything would work. He thought the unions should get hold of funds and help wherever they could, but the types of craft education would have to be settled by the several crafts themselves.

The Chairman (Mr. J. W. Sugg) said it seemed to him that architecture was an art, and although you could train a man to a mechanical business, you could not make a man an artist by any amount of instruction.

THE FRANKS BEQUEST.

THE summary of the will of the late Sir Augustus Wollaston Franks gives some idea of the character of the collections which the nation has inherited, but only his intimate friends, says the *Times*, know the great importance of the bequest. An antiquary by instinct and education, Sir Wollaston Franks aimed at illustrating, as completely as he was able, the whole of a subject by means of the many collections that he formed during his long and useful career at the British Museum. When the variety of these collections is taken into account, as well as the fact that Sir Wollaston was not, in the modern sense of the term, a rich man, it is very remarkable how nearly he attained to his ideal. The special public by whom his pursuits were most appreciated well know the scientific value of the fine series of Oriental porcelain and pottery that he gave to the Museum some years ago, and how usefully the public money was expended in the formation of the numerous and very varied sections of his department of the Museum.

Latterly, also, the visitors to the British Museum have had the opportunity of seeing the curious collection of drinking vessels which Sir Wollaston Franks deposited on loan in the new gold ornament room. The nation has entered into its

inheritance all too soon, but the "Franks Collection" will form a monument of which any nation or any collector might well be proud. It may almost be said of Sir Wollaston Franks, as is written of Wren at St. Paul's, "*Si monumentum requiris circumspice.*" All the objects lent by Sir Wollaston to the Museum now pass to the trustees. These include, besides the more valuable articles in the ornament room, a large collection of Japanese *netsuké*, those fascinating little carvings which represent in miniature all the folklore, the daily life and the mythology of Japan, and a collection of sword guards of the same ingenious and artistic people. These two series have been brought together to show, as far as possible, the range of the subject, the artists who worked upon them, the variety of the designs, as well as the range of material employed, and although larger collections may exist, it is not probable that they illustrate the subject more fully. Almost the last work upon which Sir Wollaston was engaged was the preparation of the catalogue of a collection of Continental porcelain which he had brought together in his house in Victoria Street. A few months before his death the collection was lent to the Bethnal Green Museum, and the catalogue printed. This collection will in due course also be placed in the British Museum, where it will complete what may be called the ceramic cycle. His English pottery and porcelain, Italian majolica, German, Dutch, and other wares are already there, and this small but carefully-selected series fills the obvious gap. The Trustees of the British Museum have also made a judicious choice from the collections remaining in Sir Wollaston's house, and these are now exhibited in temporary cases in the Asiatic Saloon at the Museum. There is, however, but little of first-rate importance among these, as the choicer specimens had almost all been already removed to the Museum, either as gifts or as a loan.

The two series which will probably attract most attention when space can be found to show them are the finger-rings and the personal ornaments. Upon these Sir Wollaston spared neither money nor pains, and the result, at any rate so far as the rings are concerned, is unquestionably the finest collection in the world. Over 3,000 in number, they include rings of the greatest interest and many of historical importance. Among the Greek rings are several of the finest classical work, and of the same period is the ring of a Persian king of the fourth century B.C., whose name is inscribed upon it to be used as a seal, but the scholars have not yet settled the English form the name should take. The Roman series have several of the heavy gold rings worn by fops of Martial's time. These are of great weight, nearly two ounces in one instance, and though they are set with a stone, this is innocent of engraving, as it might then be useful as a seal, and tend to diminish the owner's pleasure in a costly and entirely useless ornament. Martial describes how these rings, being worn on the upper joint of the finger, were apt to slip into the dish when the elegant wearer was at meals. Of later times the ring of Ethelwita, the sister of Alfred the Great, is, or should be, well known, as it has been shown in the Gold Ornament Room for some time past: but as it is from the English side probably the most important ring in the collection, it should not be forgotten now. In Mediæval times rings were in great request as signets as well as for mere ornament, if not for the protection of the wearer against the attacks of sickness or of his fellow-man, or even of supernatural agencies. Rings to procure invisibility had to be engraved with the quotation, "*Jesus autem transiens per medium illorum ibat;*" others are set with a "toad stone," a gem of rare virtue, now determined by science as the palatal tooth of a fossil ray; a third variety is made of asses' hoofs, and so on through the many quaint devices adopted by Mediæval and modern credulity. In all these varieties the Franks collection is rich, and many volumes would need to be written to fully explain all the allusions to be found either in the form, material or device of this curious class of rings. Of historical rings of later period than that of Alfred the Great there are many, especially of the Stuarts. Charles I. is well represented by about half a dozen nearly contemporary portraits set in rings, and the Jacobites executed in 1746 are recorded on a minutely-enamelled ring, of which, by a strange coincidence, there is an exact duplicate already in the Museum. An object of considerable rarity, apart from its historic interest, is a cameo portrait of Madame de Maintenon on a ruby about the size of a sixpence, the stone being, moreover, of the approved "pigeon's blood" tint. It is not possible to do more than to mention the large series of posy rings, or that, nearly as numerous, of mourning rings. The custom of wearing these somewhat doleful ornaments was in great fashion in England during the whole of the last century, but as a fashion seems scarcely to have gone beyond our own island.

The collection of jewellery includes many fine pieces of the fifteenth and two following centuries, but it is somewhat difficult, if not tedious, to describe them in detail. It is to be hoped that the Museum authorities will be able to make speedy arrangements for showing them to the public, though to those who know the Museum best the task does not seem an easy one. Of all Sir Wollaston Franks's collections that which most

gratifies his archæological friends is the wonderful gold "Treasure of the Oxus," a series of objects of all kinds recovered from the bed of the river. It was his intention to give an account of these in a handsomely-illustrated volume. The artistic and antiquarian problems they bring forward would fully justify their publication on the same scale by the Government.

The British Museum can scarcely hope to find again an officer who will so freely give up his purse, in addition to very exceptional talents, to the enrichment of the collections, and the public, as well as his many friends, may justly call upon the Government, on its side, to show its appreciation of such rare liberality not only by publishing the many treasures so easily got, but by continuing and amplifying the collections so well begun.

THE MOLE ANTONELLIANA.*

THE city of Turin, Italy, possesses a structure which is, without doubt, the loftiest building in Europe, and the most venturesome piece of construction in the world. This is the "Mole Antonelliana," so-called by general consent in honour of the venerable and skilful architect who conceived the project and personally superintended every part of the construction with the greatest care and watchfulness. The peculiarity of this remarkable work consists, principally, in its light skeleton construction with common bricks and lime mortar,† whereby a small quantity of material, and that of the most common kind, is employed to enclose a large building and carry it, with safety and stability, to the unprecedented height of 538 feet above the ground. The method of construction and the novel application of brick masonry in structural forms adapted to metal or fibrous material, make this building a unique structure in differing radically from all former monuments of masonry.

A brief history of the origin, progress and changing uses of the building is as follows:—In 1862 the Israelitish University Society of Turin, in view of that city being the capital of United Italy, determined upon building an imposing structure which should serve at once as a grand synagogue, college and administration building. A competition was instituted during that year among the architects of Italy to produce plans of a building that should satisfy their various requirements. Many plans were submitted, but none were considered satisfactory for the purpose, and after much discussion Professor Antonelli, of Novara (a master of architecture and engineering, who was then over sixty-five years of age, and who had erected the lofty and notable dome over the cathedral at Novara), was employed in 1864 to plan and construct such a building as they required. Under his advice and management the present structure was commenced and carried by the Jewish Society to a height of 240 feet from the ground, or about three-quarters of the height of the great square dome.

The plan as devised for the Society consisted of a building 130 feet square, with a projection 18 feet by 36 feet on each flank, containing stairways to all the main floors, and a front portico, 16 feet by 90 feet, with steps to the principal floor. A lofty basement, all above ground, was divided into two storeys to accommodate the college and administrative department, while the grand synagogue was above. This consisted of a clear, lofty room, about 90 feet square, surrounded with columns, six on each side (counting corner columns each time); outside of these columns are the walls, distant about 15 feet, thus making an aisle or ambulatory all round. Above this ambulatory, at a height of 17 feet 6 inches, is a gallery designed for women (now changed to a grand loggia). At a still greater height, just above the first offset, was designed a beautiful exterior gallery extending all round the base of the dome, with a colonnade of graceful granite columns. As will appear later in this paper, the omission of this granite colonnade on economical grounds greatly added to the difficulties of construction of the dome. There were also three interior galleries, the highest being 80 feet above the floor of the synagogue. The dome itself was originally designed to be surmounted by a cupola about 100 feet in height, divided into three storeys.

As before stated, the building was commenced in 1864. Before the base of the dome was reached the need of retrenchment in cost was apparent and the architect was directed to omit the granite colonnade forming the exterior gallery below

the springing of the dome. Notwithstanding this was designed to produce equilibrium on the arches below, Antonelli ingeniously overcame the difficulty and proceeded with the work.

In 1869, the funds being exhausted and the Jews frightened at the greatness and unusual boldness of the project, together with the discouraging fact that Rome and not Turin was to be the capital of Italy, work was abandoned, and the unfinished and unprotected structure was left exposed, both outside and inside, to the elements. No sooner had the work ceased than reports were spread that the structure was defective and would soon crumble to dust.

The Municipality, which at the beginning had accorded a subsidy to the Jews towards its erection in proportion to that granted the Roman churches, now called a council of men, expert in art and science, to deliberate on the subject. These, after carefully examining the work, reported in writing, in March 1871 that the building was safe and sound, and needed only a "hat and shirt" to protect it from wind and rain; that it needed the termination and covering of the dome and the adornment of the drum with an exterior gallery, since "without that the edifice would appear a disproportionate heap and an intolerably ugly deformity." The cost up to this time had been about 120,000 dols., and the architect estimated that 12,000 dols. more would finish it as designed.

For some months nothing was done. The destruction of the cupola was suggested, but protested against. In 1872 the President of the Jewish Society proposed ceding it to the city, but a few days after the Jews held a meeting, at which they resolved on the finishing of the temple, provided the cupola was demolished. This the Municipality refused to permit, and after prolonged discussion the building was allowed to remain as it was for several years. In 1877 the Jews sold the building to the city of Turin for 30,000 dols.—one-quarter of its cost—to be converted into a museum and dedicated to Victor Emmanuel II., and Antonelli was authorised to prepare for its transformation and completion. In the following year work was commenced on the great dome and the granite gallery at its base.

In the meantime Antonelli, with increasing confidence and assurance in his work, had projected a loftier design, which, instead of 100 feet, should place 268 feet of cupola and spire above the great dome, and make it the highest building in Europe. The perfect stability of the work up to this point, and the assurance of the architect that this great height could be erected with safety, led those in charge to yield to his ambition, and under Antonelli's personal supervision the structure was carried up to the base of the crowning statue, when, on October 18, 1888, Antonelli died at the ripe old age of ninety years. His son, who had assisted him in the supervision of the entire work, was placed in charge of the building. The crowning statue was erected in 1889, holding a glistening star 538 feet above the pavement—the greatest height reached by any structure of masonry in Europe. The interior has hardly received its finishing touches. It will probably be dedicated for a museum in memory of Victor Emmanuel II., in 1898, at the time of the Turin Exhibition.

With this brief history of the structure we will now attempt to analyse its parts and describe some of the peculiarities of its construction. The building consists essentially of a square 130 feet each way, with piers 17 feet 8½ inches on centres, showing eight piers on each side, or twenty-eight in all; at a distance of 17 feet 8½ inches inside of these are the centres of an inner range of piers, with six on each side, or twenty in all. These forty-eight piers perform all the work of supporting the walls of the building, the great dome, and lofty cupola and spire.

There are on each flank of the structure three piers supporting projecting wings enclosing stairways, and on the main front six more piers supporting the massive granite columns of a great portico. Also in the basement and sub-basement storeys there are eight interior piers which support the floor-arches up to the great square room.

Thus there are in all sixty-eight piers supporting all parts of this interesting structure. The foundations for these piers are laid in sand 45 feet below the surface of the ground. There is a sub-basement 17 feet 8 inches deep below the basement floor or pavement level, and at this point we see the commencement of light-arched construction which is to form the principal characteristic of the building throughout. At this level the interior piers are about 4 feet by 4 feet, and the exterior piers about 4 feet by 6 feet. Instead of massive walls to resist the earth pressure and support the exterior walls, thin segment arched walls are sprung from pier to pier with convex side outward; these in turn are buttressed and strengthened by horizontal arches at mid-height of the sub-basement.

From the level of the pavement the outside walls are carried on flat arches from pier to pier, thus throwing all weights of walls, floor and contents on the piers. The three floors that intervene between the sub-basement and great temple are carried on remarkably light arches, some of them over 30 feet span and less than 3 feet rise. The loggia and gallery floors

* A paper by Mr. G. W. Percy read before the Technical Society of the Pacific Coast.

† The bricks used throughout this building are the common bricks of Northern Italy, measuring 2½ inches by 5½ inches by 9½ inches, with a crushing strength of about 100 tons to the square foot. The mortar is made from lime slaked and buried in pits for a year or more and used with a proper admixture of sharp sand; no cement whatever is used in the work. The actual load on most of the supporting members is about 15 tons per square foot, which must be largely increased at times by wind-pressure.

are also carried on very thin and light brick arches employed with the greatest freedom in every part of the work.

The external architectural features of the building consist, first, of a basement storey treated as pedestals for the pilasters and columns above; then two orders of architecture, consisting of brick pilasters over the main piers, with granite Corinthian capitals. The walls between the lower pilasters are ornamented with small granite columns in two storeys, with windows in the central spaces. The second order has a high brick screen wall with small granite columns, all open to the loggias before mentioned.

Above the cornice of the second order is the roof of the side projections and the front portico, and an offset of about 5 feet all around to the base of the great external gallery, with its fine granite colonnade around the base of the dome. Over this gallery is another sloping offset of about 5 feet to the base of the great square dome.

This portion presents five large arches on each side, with ornamental pilasters and entablature, which forms the springing line of the great dome, about 150 feet above the ground.

The great dome itself, 100 feet square on the outside and 120 feet high, has its sides falling inward about 35 feet, forming a square at the top of about 30 feet; on this is erected a combination of cupolas and spire, with granite columns and brick piers, crowned with a statue 268 feet above the dome, or 538 feet above the pavement. The architectural effect, grace or proportions of this building we do not wish to criticise or praise, but only call attention to the difficult problem presented and the skill with which it was solved.

The problem before the architect was to poise on this inner and outer square of slender supports a great square dome which should have its thrusts self-contained, be of such light construction that it should not crush the supporting columns and of sufficient strength to carry a lofty cupola and spire, and to support itself through the various stages of construction without interior centreing.

Antonelli found by experiments that bricks would lie in equilibrium on a bed of mortar at an inclination of 30 degrees with the horizontal. He therefore arranged the pitch of the dome so that the greatest inclination of the radius should not exceed 30 degrees. He allowed 6 feet for the entire thickness of the dome, and placed the inner line, or shell, directly over the inside line of columns.

The elements of the dome then become established as follows:—

Interior side	88 feet
Thickness	6 "
Exterior side	100 "
Interior radius	246 "
Exterior radius	252 "
Height of dome	120 "
Base of cupola at top of dome, inside	16 "
Base of cupola at top of dome, outside	30 "
(Small fractions of a foot omitted.)	

With the inside shell of the dome over the inner line of columns, and the thickness 6 feet, with the columns 17 feet 8½ inches on centres, it is evident that the outer shell would be about one-third of the distance to the outer line of columns, and to properly support this and place the dome in equilibrium on the two ranges of columns was the first great difficulty encountered. This might be easily accomplished with strong metal beams extending from column to column, capable of supporting the load at any point, but it was Antonelli's purpose to use brick arches everywhere to support loads, using metal very sparingly and only as ties and keys, and thus we find him preparing for this great load in the following manner:—

Over the granite capitals of the second storey of columns, and at a height of 75 feet above the ground, parabolic arches are sprung from outer to inner columns, with metal tie-rods and flat groined arches to form the ceiling of the loggia.

On these transverse parabolic arches, which it will be remembered are only the width of the columns and 17 feet 8½ inches apart on centres, are sprung two elliptical, longitudinal arches, dividing the space between columns into thirds, the inner line of these arches destined to carry the outer shell of the dome and the outer arches to support the granite exterior gallery, which we now see was designed to load the parabolic arches symmetrically quite as much as for other use or ornament.

It was after these arches were turned and the base of the gallery built that the architect was required to abandon the granite gallery to save expense. Probably no one realised, as did Antonelli, the importance of this gallery as a counterpoise to the weight thrown on the inner side of the arches, or the skill and care it would require to prevent the parabolic arches from being very unsymmetrically loaded, with resulting displacement.

We shall see, however, how ingeniously Antonelli overcame the difficulty and moved on to the construction of the great dome. Considering these arches capable of carrying a portion

of the load unequally distributed, he proceeded with the vertical supports of the dome, consisting of two orders of columns inside and square brick piers outside, with a blank wall to receive the roof of the gallery when it should be built, and over what should be the roof of the exterior gallery he turned five great semicircular arches on each side, which were to form large clerestory windows to light the interior and form architecturally the drum or base of the dome.

We have now arrived at a height of 150 feet above the ground and at the springing line of the great dome, and here a peculiar construction commences, such as one might design in iron, but which few would think of executing in brick and lime-mortar.

It was necessary that in order to place such a lofty structure as was designed on such slender supports, it should be as light as possible, elastic and strong. In metal or timber this would not be a difficult thing to do, but in masonry it required a departure from all former efforts, and to accomplish which consummate skill in design, exactness in calculations of forces and stress, and the greatest care in workmanship and selection of materials were required.

It will be remembered that the entire thickness allowed for the dome was 6 feet; an inner shell was necessary to form a ceiling surface, and an outer shell on which to lay the roof covering. These the architect made as thin as possible—only one-half a brick, or about 5 inches each. The real supporting members consist of vertical ribs placed directly over the main supporting columns, 17 feet 8½ inches on centres. These ribs consist of an outer and inner member, about 10 inches by 15 inches each, connected at intervals of about 12 feet with cross arches, upright and inverted, with an iron tie-rod through each connection.

At each of the four corners are somewhat larger ribs or spines placed diagonally on the plan, constructed in a similar manner to the vertical ribs, and destined to carry the entire weight of the cupola and spire. The vertical ribs all join the corner spines in pairs, and their principal duty is to support the square dome, the two middle ribs on each side joining the angle spine at the top, where the base of the cupola rests. The distance between the vertical ribs is divided into three parts by smaller ribs one brick square, through which iron rods pass about 5 feet apart, to secure the granite ribs on the outside of the stone covering.

The inside shell is also strengthened by similar small ribs projecting into the space between the shells, and further supported, while the entire structure is braced by curved ribs projecting with two offsets about 10 inches on the inside of the dome. These curved ribs are struck with the same radius as the inside shell of the dome, and branch each way over every one of the interior columns, intersecting each other at acute angles and abutting, two by two, at the corners, thus dividing the interior surface of the dome into symmetrical panels with curved lines, and serving to distribute any weight or force acting on any of the spines to the several columns.

In building these curved ribs some interior support may have been obtained by struts and braces from the timber scaffold which was erected inside the dome, but no complete system of centreing was employed.

The large panels between these curved ribs, only half a brick thick, are built slightly concave or sail-like, to prevent their falling inward while the mortar was still fresh. This concavity, however, is so slight it cannot be perceived from below. At five different stages in the height of the dome horizontal arches are sprung from rib to rib, with thin arched floors spanning the space between shells and forming so many ambulatories around the entire dome, and making rigid connections of the various parts.

At the same time wrought-iron ties are placed near these floors to resist any possible tensile strain that might come from the outward thrust or from the tendency to fall inward during construction.

Thus it will be seen the entire composition of this dome is a complicated piece of framing and trussing, with all the members in brick carefully proportioned to the work they have to perform, while iron ties are inserted only where tensile strain may be encountered.

As if the difficulties of carrying out this design were not sufficient, the necessity of omitting the external gallery required some device to throw more of the weight of the external shell on the inner columns than was first proposed, and thereby relieve the parabolic arches before described. This was accomplished by carrying the inner member of the principal ribs in a vertical line, and inserting granite blocks extending entirely through the dome, and by vertical piers above the granite, throwing the weight of the outer shell to the inside line. This device proved successful, and no movement was apparent in the unequally loaded arches below. Stone stairs are built into the space between the two shells of the dome, thus giving easy access to the cupola above.

This stage of the work was reached in 1880, and before proceeding further the granite gallery so often referred to, and so

much needed both to give symmetry to the building and equilibrium to the parabolic arches, was constructed; also the covering tiles were placed on the great dome. These consist of slabs of dense flagstone, about 2 inches thick and nearly 6 feet long, extending from centre to centre of the small brick ribs, while the vertical joints were covered and the whole secured with granite ribs carefully fitted to the slabs and held in place with iron bolts extending through granite and brickwork and keyed-up on the inside.

A notable feature in all the iron connections throughout is that they are made in the old method of keys and wedges, instead of the more modern thread and nut. These bolts, placed at regular intervals and in horizontal rows about 5 feet apart, are formed with eyes on the outside, by which scaffolding may be secured.

One would suppose that when the top of the dome was reached, 275 feet from the ground, most architects would consider it desirable to finish the work with a cupola or lantern of moderate height: but not so with Antonelli. Not satisfied even with a three-storey cupola, 100 feet high, which was first designed, he proposed an astonishing combination of cupolas and spire, and which required a further height of 268 feet and a superimposed weight of about 550 tons.

By this time we should be prepared for any venture the bold architect might make, and while we may be amazed at the slender construction placed at this great height and poised on such delicate supports, we shall find nothing more surprising than that we have examined.

As before stated, the converging ribs and spines meet at the top of the dome in such a manner that when connected with strong arches and iron ties they form a platform 30 feet square on the outside, with an opening 16 feet square in the centre, and the arches so constructed that all weight placed on this platform will be conveyed to the angle spines and distributed by the straight and curved ribs to all the columns below.

The base of the cupola, about 10 feet high, is formed with six bracket-like piers on each side placed over the outside arches, and four piers on each side over the inside arches. The brackets on the outside support a granite balcony, from which a superb view of the city and surrounding country is obtained. Above this base are high pedestals, and two storeys of granite columns on the outside line and brick pilasters with windows on the inside, with all connecting arches of brick.

This lower section of the cupola terminates with stone pediments on each of the four sides and a conical-shaped roof above falling in about 5 feet, and consisting of a thin shell one half-brick in thickness, stiffened with ribs and girts of a whole brick on the inside.

The top of this conical roof carries us 75 feet above the dome, and here the structure assumes a circular plan, with an outer and inner row of small granite columns, and inside of these another circle of very small brick columns, between which and the inner circle of stone columns are double flights of winding stairs of stone.

The outer circle of columns is but one storey high, and supports another outside balcony, crowned in the design with eight angels, presumably blowing the last trump.

The stone columns of the inner circle now become the outer ones, and extend two storeys higher, with the stairs and inner columns as before described. And now, at a height of 135 feet above the dome, a slender spire is built for a height of 65 feet, consisting of eight brick piers, about 10 inches by 10 inches, forming the angles and connected with the stone roofing slabs, held with stone ribs on the outside, bolted through the angle piers, and braced on the inside by the stone stairs. The inner circle of brick columns has now become very small, with only about 16 inches of a well-hole in the centre. The stone stairs, now reduced to a single flight, continue to wind around the central shaft of brickwork, and reach another stone balcony 205 feet above the top of the dome, or 475 feet above the pavement, the highest point to which the public is admitted.

Again we are treated to a storey of stone columns, tied together with iron bands, the central hollow shaft of brick, and the stone winding stairs to the last open balcony that may be reached by stairs.

As the exterior diameter is here reduced to 6 feet, the stairs are no longer practicable, and those who would reach the higher balcony must ascend an iron ladder on the outside of the slender spire.

The final and crowning statue is still elongated, as if determined to get as far as possible from the earth, and the whole is very appropriately surmounted with a star, which we hope will remain a fixed star for many years.

New Roman Catholic Day Schools, erected at a cost of 4,000 $\frac{1}{2}$., have been opened at Batley by the Right Rev. W. Gordon, Bishop of Leeds, who was formerly priest-in-charge of St. Mary's Church, Batley, where his brother, Father Charles Gordon, is at present pastor.

YORKSHIRE ARCHÆOLOGICAL SOCIETY.

THE second excursion organised by this Society took place on the 22nd inst. The members and friends, meeting at Milford Junction and taking carriages, proceeded to Steeton Hall, which, according to a pedigree of Reygate, in Foster's "Yorkshire Pedigrees," was held by the Reygates from the time of Henry III. down to 1375, when John de Reygate, the last male representative of the family, died. The numerous shields were carefully examined, and the vaulted room and other fragments of Mediæval work were a source of interest to the visitors. Ledsham Church, which was given to Pontefract Priory by Robert de Lacy, was next visited, and Monkfryston, so called because the Benedictine monks of Selby were the owners of the place, proved to archæologists worthy of consideration. Passing on to Birkin, the church of that place was surrounded with many items fascinating to strangers, the principal feature being that it is one of the most perfect examples of a small Norman church to be found in Yorkshire. With the exception of the addition of an aisle, it was found that it had been very little altered. Brayton was the last place visited, and there the church was gone through. The earliest part of the present structure is of about the same date as the Norman work of the church at Birkin, and represents a church built under the same influence, but on a larger scale. The tomb of George, Lord d'Arcy (1558) and the arms thereon were matters which proved exceptionally interesting.

Mr. William Brown, the secretary, gave historical notes on each church visited, and Mr. J. Bilston submitted the architectural descriptions. The company then drove on to Selby.

TESSERÆ.

Romanesque and Gothic.

THE principal quality which we may find invariably vindicated by Romanesque architects or those who connected the traditions of classical art through various types with Mediæval art consisted in a knowledge of the effect of vastness produced by the multiplication of regular subdivided parts, equally subdivided themselves in their turn. The long rows of columns which decorated the early Christian churches, the arcadings, which ultimately formed one of the principal characteristics of the style, all exhibited excellent ideas of general effect cast into often uncouth and eccentric detail. Yet in all this uncouthness and these eccentricities there may be perceived vigour and life indicative of the state of germination, a casting off, as it were, of an old skin to put on a new one, and after the throes of labour to give birth to an entirely new creation. As otherwise than an entirely new creation it is impossible to regard Mediæval architecture. If it should be necessary in a single word to state what appears to be its dominant sentiment, it is possible that the word "aspiration" might, better than any other, convey that elevation of sentiment which induced men to lift their structures as they lifted up their hearts towards the Supreme Power which reigned over them. Men's mind and men's architecture rose together upwards, and as the old predominance of horizontalism had shown men thinking of themselves and running parallel with the soil, "of the earth, earthy," rather than breaking away from it, so the vertical tendency of the Mediæval architecture seemed to be expressive of a springing from the world to a something higher and purer.

Early Bricks in St. Albans Abbey.

The brick is mostly of one size, namely 16 by 12 by 1 $\frac{1}{2}$ inches, and no less regard was paid to lapping the courses or preserving the bond than could have been in the construction of masonry. Hence we observe the influence that the material exercised over the design; the retreating members on the angles of the piers and arches, and on the pilasters standing in advance of the walls, are in proportion to the measure of the slabs. Brick of a still larger superficial dimension than that just named appears occasionally, particularly in the staircases, but in point of substance it generally varies; this inequality, however, was unimportant, the concrete mortar was used with an unsparing hand and with a confidence which showed perfect reliance upon its temper for duration; and in cases of disparity an approach to a level line in laying the courses was obtained by giving more or less substance to the joints. The bricks vary in shape and durability in proportion to their exposure to the fire in the process of burning. Many are vitrified and warped by excessive heat, and but few are observed to have yielded to the action of the weather upon the exterior of the building. The earth of which they were made was evidently prepared with great care; their texture is close and fine, and the hardness such that they seem as durable as the flint with which they have been so admirably combined in the walls. They are mostly of a deep red colour, but many in the interior of the belfry are of white earth.

The Fortifications of Messene.

The gate of Messene is the most beautiful and the most massive defensive structure which has come down to us from the historical period of Greek antiquity. It is in excellent preservation, and where there may chance to be a defect it is scarcely perceptible. The whole gate is magnificently hung with dense shrubbery and a profusion of creeping plants. It seems, as Curtius remarks in his description of Messene, as if we were entering a city forsaken only a short time before. We stand before a ring of massive masonry. Two square towers flank the entrance, protecting a doorway about 15 feet in breadth. Through this we pass into the inner court, which is a perfect circle, with a diameter of 62 feet. The wall forming its circumference is in good preservation to the height of nine courses of stones; these are clean, well-smoothed blocks, laid with great care and skill. Below there is first a belt of stones, in length double their own height; then comes a layer in which the height preponderates considerably over the length, then another belt corresponding exactly in form and height to the first; after that uniform courses of blocks, so finely cut and so firmly joined without cement, that they look as if they had grown together. A niche on each side of the entrance shows that this magnificent court did not want the adornments of statuary. A second doorway, exactly opposite the first, leads directly into the city over a broad paved way. The huge lintel, 18 feet in length, rests with one end upon the ground. Green ivy clusters all around it. The city walls, after ascending Ithome and Evan, return again into the valley and meet on the east in a second gate, little of which is preserved, and which probably never equalled the west gate in grandeur. These walls are of the most imposing character. Square towers, and, at sudden bends, round ones, break their continuity at determinate, though not always regular, intervals. Pausanias says of these walls:—"The Babylonian walls, or the Memnonian walls at Susa in Persia, I have not seen, nor have I spoken with anyone who has seen them; but this I know, that the Messenian walls are stronger than the walls of Amphyres in Phocis, of Byzantium and of Rhodes, which are reckoned the most strongly fortified places." Our astonishment increases when we learn that these gigantic defences were erected in a very short time; Diodorus says in the space of eighty-five days. What a tough, practical vigour in political matters Greece manifested even in her decay.

Thirteenth-Century Plans.

Everywhere the ground plans of the twelfth century owed their origin to Byzantine influence, as in such churches as St. Mark's at Venice, or to Romanesque influence, as in the Roman basilica, converted into a church, and then copied in spite of its history. The former plan was symbolical, with a central dome and a cruciform arrangement of nave, transepts and choir, whilst the latter was simply practical and useful, and a good meeting place for people for religious as well as for secular purposes. The steps were many by which these two plans were gradually fused and developed into the perfect French thirteenth-century ground plan. One of the most suggestive of them is to be seen no doubt in the churches of the Puy de Dome, where with the simple nave and aisles, recalling the basilica, we see the Byzantine central lantern, the transepts, and finally the apsidal east end, with its surrounding aisle, and a range of chapels projecting from the latter. Here everything is simple and austere; the round arch only is used, and it requires some consideration to detect in it what one may nevertheless pronounce to be the first type of the very best French Gothic. Go from these early churches of the Puy de Dome to Bourges, and so to Paris, Chartres or Rouen, and you will find the same general scheme translated, so to speak, into Gothic; clusters of columns take the place of simple shafts, their capitals are exuberantly sculptured, the roofs are vaulted with pointed vaults of stone, the windows are delicately designed with geometrical traceries, and the arrangements of all the constructive features are made with the most consummate art and care. It is well to pause on this type of plan for a time, because for some reason it was never extensively employed in England, where there was a decided prejudice against the apsidal termination to a church after the end of the twelfth century. Otherwise, in most respects, the English churches are more varied in plan than the French; and one possible reason is that from the early part of the thirteenth century the French, wherever it was possible, groined their churches in stone, whilst the English almost as invariably covered theirs with timber roofs. The former required, of course, much more careful arrangement of the plan in order to give the required points of support and the necessary buttresses; the latter led to greater variety of outline, and to a less formal and scientific style of design. The architect was able to wander at will over the whole field of art, to vary the outline of his building wherever he listed, and to make changes in his disposition of the piers and other main supports of his building, which were quite impossible when the building was to be groined in stone.

Ornamental Pavements in England.

The use of marbles or other like costly pavements was almost unknown in England, even as it would appear during the time of the Roman dominion, for few examples are found of any importance, and during the Middle Ages the porphyries brought from Rome to adorn the Chapel of the Confessor in Westminster Abbey during the reign of Henry III. might be mentioned as a solitary instance of the use of such materials. The mosaics of the Classical age were succeeded by the rich pavements now found almost exclusively in the earlier Italian churches. It is not improbable that the wealthier pilgrims on returning from Rome would endeavour to ornament the churches of their own country in some like manner, as it is recorded that they brought back from Italy paintings and sacred ornaments of various kinds, and that foreigners were engaged to visit England in order to glaze the windows of churches. No example, however, of such ornamental pavement had been recorded, nor is it known of what nature were the pavements designated by the Saxon term, *bleo-stæning*. In later times pavements were formed of square tiles called *quarrels*, composed of red clay, with ornamental designs in white clay imbedded in cavities impressed upon the surface of the quarrel and glazed. Occasionally coloured glazes were employed, or the quarrels were ornamented with impressed designs only, such as those found in Ireland, described by Professor Oldham. Decorative tiles have improperly been designated as Norman. Numerous specimens may be found in France, but a far greater variety in England, where the manufacture seems to have been practised in great perfection from the thirteenth to the sixteenth century. Higden, the chronicler of the times of Richard II., speaks especially of white and red clay to be found in England valuable for fabricating pottery and for colouring tiles, comparing it to the true "Samian." The introduction of such pavements enabled the architects of the Middle Ages to produce a more complete harmony of effect in the interior of sacred buildings, serving to maintain throughout the structure the character of rich decoration produced by painted glass, hangings, and especially by the coloured designs which covered the walls, mouldings and vaults. In the choir or chancel, more particularly, the use of ornamental pavements prevailed. Some examples remaining in England may serve to show the general rules of arrangement—as displayed in the Exchequer Chamber at Exeter. The pavement of Prior Cranden's Chapel at Ely supplies an interesting and peculiar example, combining figures with ornaments of the more ordinary kind. The most remarkable productions of this nature upon record are the sepulchral effigies designed upon flat tiles, formerly existing in the abbey church of Jumièges and at Fontenay near Caen, of which a description was given. The abbey church of Jervaulx, in Yorkshire, formerly exhibited one of the finest pavements known to have existed in this country.

Illumination of Manuscripts.

The practice of introducing ornaments, drawings, emblematical figures and even portraits into manuscripts obtained in the works of Varro, Pomponius Atticus, &c. From the fifth to the tenth century the miniature paintings which we find in Greek or Byzantine manuscripts are generally good, as are some in those of Italy, England and France. From the tenth to the middle of the fourteenth century they are commonly very bad, and demonstrate the barbarism of the age. Towards the end of the last period they improve much, and in the two succeeding centuries many excellent performances were produced, especially after the restoration of the arts and revival of ancient works. About 1546 the illuminators were in great distress for want of employ, on account of the dissolution of abbeys and the invention of printing. The last specimen was Cardinal Wolsey's lectionary at Christ Church, Oxford. Gold and azure were the favourite colours of the illuminers, and a metal pen was used. Books illuminated with superior beauty were for persons of distinction; and the works destroyed at the Reformation were chiefly such as were illuminated, because erroneous and superstitious.

Apollodorus the Architect.

It is supposed that Apollodorus was born at Damascus. He obtained the favour of the Emperor Trajan, and was engaged on the architectural and engineering works constructed during his reign. Among them were the square in Rome, with the column in Rome, a triumphal arch, a college, a theatre for musical performances, the Ulpian basilica, a library, baths, temples, roads, aqueducts, the great bridge over the Danube. His Forum of Trajan excited the envy of Hadrian, and in consequence the architect was driven into exile on some frivolous pretext. The Emperor, in order to convince Apollodorus that he could easily dispense with his services, sent him a design for the Temple of Venus and Rome, and his opinion on it was asked. It had been prepared by Hadrian. Apollodorus answered that the emperor should have made it more lofty, and have introduced accommodation below the ground for the reception, whenever occasion required, of the machinery of the

adjoining amphitheatre, and have imparted to the façade of the temple towards the Via Sacra a more imposing aspect. The statues, which were represented as seated, were said to be so disproportionate, that if the goddesses desired to stand up and walk they would not be able. As might be imagined, the artist paid for the freedom of his criticism with his life.

Paris International Fire Prevention Congress, 1897.

SIR,—As British Secretary of the above Congress, I have been asked to hand you the enclosed letter from the President of the Paris committee, invoking your kind and valuable assistance to the project. After the ample remarks of the President I have little to add, but simply that I think France requires in this matter to get assistance outside her own country, and nowhere, I venture to assert, can she get it better than in England. If you can see your way clear to ventilate the matter in your valuable journal you will be rendering an everlasting service to humanity. Before doing so, if you wish for any further explanation from me in person I shall be pleased to wait upon you or meet one of your representatives here at any time by appointment.

On my own part, I enclose you copy of the committee, showing the great influence at work in Paris, to which I shall feel honoured if you will permit me to add your name.—Believe me to remain, yours faithfully,

FREDK. HOARE.

Sir,—We have the honour to inform you that, in the hope of preventing a return of the horrible catastrophe of the Charity Bazaar fire of Paris in May last, which has so painfully affected the world, we propose to call together an International Congress to discuss all means to prevent and minimise fire in theatres, concert-halls and places of public resort, the date of which will be very shortly announced. We therefore appeal to the Press, to French, English and foreign architects, engineers and scientific men generally, who are interested in this grave question.

In conjunction with the Congress is also being organised an international exhibition of all engines, inventions, products and plans for the prevention of fire, and fire-extinguishing appliances and materials. We therefore invite all manufacturers, engineers and inventors to exhibit their machines and inventions there, for which purpose a vast building will be placed at their disposal next to the Congress. In this way all scientific discussion will be strengthened by practical demonstration.

To prove the importance of the Congress 150 members of the Senate, deputies, municipal councillors of Paris and scientific men of the Government have already joined the committee.

We sincerely hope, Mr. Editor, that you will kindly favour us with the help and support of your important paper to carry our appeal to the knowledge of your numerous readers, thereby rendering a lasting service to our committee.

We have appointed as our British secretary Mr. Frederick Hoare, of College Chambers, 249½ High Holborn, who will be pleased to receive on our behalf all expressions of sympathy with the movement, and gladly welcome in the name of the committee any data or useful information bearing upon the business of Congress.—Yours faithfully,

MARECHAL,

Vice-president of Committee.

Liskeard Church Tower.

SIR,—As usually happens in a weak case, the letter from Mr. Norris in your issue of July 23 inclines more to personal attack than to honest argument. Because, as the result of Mr. Norris's invitation for *bonâ fide* criticism and his statements in public, letters not agreeable to his view appear in some of the local architectural papers, the subject has become "nauseous" in his eyes, and he attributes wholly unworthy motives for my opposition to his scheme of destruction.

Now, sir, although I adhere to the opinion expressed in my report in every detail, I am not going to occupy your valuable space or waste time in defending the suggestions it contained. My only desire is to do all in my power to save the old tower from wanton destruction, and if means better than mine are suggested, no one would welcome them more than myself, if the final result is the same.

But, to confine myself to the subject of discussion, what new reasons does Mr. Norris give for the demolition of the tower?

1. There is a somewhat amusing description of the tower as at present—a description that is in a measure true, in that the tower certainly shows the results of both disgraceful neglect and ignorant and unsightly repair. But the evils

from the former cause can even at this late hour be remedied, while the objectionable slate and stucco surface can easily be removed.

2. A curious statement that "the rebuilding scheme of this tower is not the dream of a night, but the dream of 400 years." What a nightmare. How on earth could Mr. Norris have arrived at this conclusion? Do records establish the curious fact that the Liskeard community have been wanting a new tower since the fifteenth century, and have been unable to raise the funds in 400 years?

If such is the case, it is unique in the history of church building.

3. A still more curious statement as to the intention of "the gentlemen of the fifteenth century who nobly built this large Perpendicular nave—"would have erected a tower worthy of their new nave had their cash been sufficient."

Again I ask, how is this marvellous insight obtained as to the intentions and impecuniosity of the gentlemen of the fifteenth century? It is, of course, purely imaginary, like the dream, and surely in the absence of documentary evidence to the contrary, we can but deal with facts, and accept the explanation taught by numerous other examples, that such ancient work was always valued and generally retained where possible.

4. The last question brought forward as an argument is almost comic in its very simplicity. "Why did they not rebuild a Norman nave?" Why were repairs in 1627 not carried out in the Norman style?

Who ever heard of the fifteenth or seventeenth century architects building or rebuilding in the Norman style? No, sir, the simple fact probably is that more accommodation was necessary, and therefore a larger nave was built, of course, in the style of the period in which it was built. A new tower was not necessary, therefore they, of course, retained the old one.

The doorway added in 1627 simply goes to prove that they meant to keep the old tower.

One other point. Mr. Norris objects to the photo of the tower published in your issue of July 9, and insinuates that it was cleverly arranged so as to hide some of the most conspicuous defects in the tower. This photograph was most kindly taken for me, and sent to me previously to my report, by one of the gentlemen of the committee who himself supports the rebuilding scheme.

In conclusion, I can only add that, whilst I am sorry to be in antagonism with Mr. Norris and the committee, I feel that now, if ever, is the time to speak, so as to hinder or prevent, if possible, this unnecessary destruction of Liskeard's most ancient and interesting building.—I am, yours faithfully,

GEO. H. FELLOWES PRYNNE.

6 Queen Anne's Gate, Westminster, S.W. :
July 28, 1897.

GENERAL.

The Select Committee of the House of Commons on the Administration of the Museums of the Science and Art Department have agreed on their report. It describes the evidence which has been taken, and emphasises their interim report with regard to the urgency of making better provision against fire at the South Kensington Museum. The committee recommend their reappointment next session, in order that they may then continue and complete the work entrusted to them.

The Theatre Royal, Worthing, which has been reconstructed from the designs of Mr. A.T. Cooke, was formally opened on Monday evening by the Mayoress.

A Portrait of Sir John Stanley, by Romney, has been purchased for the Louvre.

The London County Council agreed on Tuesday to expend 100l. on printing a register of buildings of historic or architectural interest in London, on condition that the particulars, plans and drawings which would form the register were presented to, and became the property of, the Council. The particulars for the register have been completed, so far as the parishes of Bow, Poplar and Bromley are concerned, by the Committee for the Survey and Registration of the Old Memorials of Greater London. It is understood that the registers, plans and drawings will be presented to the Council free of cost.

The Price offered for the materials of the Palace of the Liberal Arts in the Champ de Mars on Tuesday was 308,000 francs. The contractor is to take down the structure.

During the Excavations at the Limescastell "Alteburg," near Holzhausen, in the Wiesbaden district, an inscription was unearthed at one of the gates, consisting of gilt bronze letters fixed to a slab of limestone by means of silver rivets. The inscription, dating from 213 A.D., contains five lines, and seems to be dedicated to the Emperor Caracalla in honour of his victory over the Alemanni, a victory in consequence of which he assumed the surname of "Alemannicus."

The Architect.

THE WEEK.

It is an unwise course for a builder to act in defiance of local by-laws. Courts of all kinds generally support the latter, and when a decision is given in favour of a builder the advantage is rarely worth the expense. A case has just been heard in Plymouth in which a builder announced that he intended to establish a test case, and an ambition of the kind is sure to be expensive. He was summoned for erecting small houses at the rear of other houses without leaving the 15 feet of open space between the houses and the boundary wall required by the local by-laws. His defence was that he had substantially complied with the by-laws, of which the object was to secure an open space of not less than 150 square feet. But the space was obtained by an increased width, although the length was diminished by about a foot. The defendant was fined 2*l.* and costs in each of the five cases, but what is worse, the Corporation can insist on the removal of the buildings or on the infliction of an additional penalty. So far the course of the law is not favourable to the contention of the contractor, and it is doubtful if the case be brought into a higher court whether a different decision would be obtained.

At the last meeting of the Cardiff County Council some alterations were made in the requirements which will have to be satisfied in the designs for the new municipal buildings. The site has been extended, as it will not be necessary to be hampered by the law courts which will be erected, as the courts will not be placed in the position first proposed. The journalists of South Wales drew attention to the absence of accommodation for the Press. It was pointed out that care would have to be taken to place the Press gallery in the law courts in a position where the evidence could be heard. It was said that in Manchester the gallery was placed behind the witness-box, and in consequence the reporters were compelled to appeal to the judges that they might be placed in a more convenient position. Accordingly their lordships ordered seats to be provided underneath the bench, and in front of the barristers, prisoner and witness. The local branch of the Incorporated Law Society obtained the promise of an ante-room in connection with the law library. It was also decided to arrange for a refreshment-room, a Press-room, 20 feet by 15 feet, and a deputy mayor's parlour being also be provided. The assembly-room is to accommodate about 1,000 persons, but when necessary it and the ante-chamber and council-room can be united. The estimated cost of the building, in spite of the additions, remains at 200,000*l.*

For the first time since its revival the National Eisteddfod has been held in Newport, Monmouthshire. But according to the scribes there was another assembly of the same kind in 1350, and five centuries and a half form only a brief period in Cymric history. The pavilion which was erected for the meetings, and which will accommodate 14,500 spectators, cost 2,300*l.*, and about 2,000*l.* was spent on prizes. Once more the cosmopolitan Mr. HERKOMER, R.A., was the chief judge for works of art. He declared there was an improvement visible in the quality of the work submitted. Much was produced which was not worth a place in the exhibition. He suggested that a permanent art committee should be formed, as it was difficult to improvise one. The following were the principal awards in painting and sculpture:—Oil-painting.—(1) 40*l.*, E. H. THOMAS, Cardiff, "Intellectual Blindness following Old Thoughts;" (2) 10*l.*, Miss EDWARDS, "Babes in the Wood;" commended, CHRIS. WILLIAMS, Maesteg, "The Hendre Farm," and T. PRYDDERCH, Wroxeter, "Ruins of Theatre and Mount Etna." Landscape.—(1) 25*l.* (including an extra 5*l.*, as the scene depicted is in Monmouthshire), PARKER HAGARTY, B.C.A., Cardiff, "On the Road to St. Bride's, near Newport;" commended, A. NETHERWOOD, Llandudno, "Summer," and W. J. CORAH, Conway, "Llangostein Old Hall." Water-colour drawing.—(1)

30*l.*, C. COCKRAN, B.C.A., Anglesea, "A Still Salt Pool, locked in with Bars of Sand;" (2) 10*l.*, S. TOWERS, Conway, "A Welsh Hamlet;" extra prize (8*l.*), N. STEPHENSON, Deganwy; commended, B. A. PUGH, Aberystwyth, "The Nurse," and T. PRYDDERCH, Wroxeter; and B. A. LEWIS, Carmarthen, "Ceracle Fisher of the Towy." Portrait bust from nature.—15*l.*, H. PRICE, West Kensington; extra prize (8*l.*), FRED. THOMAS, Cheltenham; commended, ETHEL HURRY and FRED THOMAS. Carved oak bardic chair.—Silver medal and 15*l.*, THOMAS HUMPHRIES, Carnarvon. Carved section.—Mantelpiece, 10*l.*, H. S. WHITE, Swansea. "Glastonbury" chair in oak, 3*l.*, F. E. KERS, Newport. Mahogany or walnut stair newel, 3*l.*, W. GLEESON, Cardiff. Carved oak picture frame with gold margin, 3*l.*, F. E. KERS, Newport. Original pen-and-ink series of six sketches in Wales.—(1) 6*l.*, B. A. PRICE, Carmarthen; (2) 3*l.*, T. PRYDDERCH, Wroxeter. "Pictorial" poster advertisement illustrative of the National Eisteddfod.—Medal and 5*l.*, B. C. EVANS, South Hampstead. Mr. A. B. PITE examined the architectural drawings, but his awards were not announced.

In the will of the late Lady WALLACE, her pictures, porcelain, bronzes, artistic furniture, armour, miniatures, snuff-boxes and works of art, on the ground and first floors and in the galleries of Hertford House, as well as the LOUIS XIV. balustrade, are bequeathed to the British nation. The bequest does not include personal and modern jewellery, trinkets and effects, nor ordinary modern furniture and chattels. The Government in return are to give a site in a central part of London, and build a special museum for the collection. It is also stipulated that Mr. JOHN MURRAY SCOTT is to be one of the trustees of the collection. The other trustees appointed by the Treasury are the Earl of ROSEBURY, Sir EDWARD B. MALET, Sir JOHN STIRLING-MAXWELL, Major-General Sir ARTHUR E. A. ELLIS, Mr. A. B. FREEMAN MITFORD and Mr. ALFRED C. DE ROTHSCHILD. Mr. CLAUDE PHILLIPS has been appointed keeper of the collection. The committee appointed to consider how the collection should be housed having recommended the purchase of the interests in Hertford House and its adaptation to a museum, a sum of 80,000*l.* will be obtained for that purpose. No arrangement could be more satisfactory. The character of the Wallace collection would suffer if placed in a new building of a severe character like the National Portrait Gallery. The pictures were specially selected to adorn a private mansion, and it would be difficult to erect one better adapted for their display than the house in Manchester Square. Mr. WATERHOUSE acknowledged that at first he was not in favour of keeping the collection there, but on considering the decoration of the rooms and their matchless chimneypieces, he came to the conclusion that if the bequest were taken away from its present surroundings it could never be shown to such advantage.

ACCORDING to ROUSSEAU the French have no respect for ancient monuments, and he was acquainted with too much destruction to be in doubt on the subject. But such devotion to antiquity as was exhibited by AUGUSTIN CARISTIE, the architect, in dealing with the triumphal arch and theatre at Orange, was almost enough to compensate for high-handed proceedings elsewhere. He was born in 1783, and from 1805 until 1856 he was connected with Orange. He lived amidst the ruins, and in order to give an example of reverence he worked as one of the labourers. After his removal to Paris, where he died in 1862, the restoration of the Roman theatre was neglected. M. DAUMET was appointed as successor to CARISTIE, but either from want of money or from doubts about the advisability of operations in such a place little progress was made. Under M. FORMIGÉ, who has charge of the ruins, more energy is now exhibited, but he is as reverential as M. DAUMET, and his aim has been to stay destruction rather than to attempt restoration in the French sense of the word. He has, however, made the seating safe, and now 10,000 spectators are able to enjoy the appearance of the actors of the Théâtre Français in plays founded on classic subjects.

SIR EDWARD POYNTER, P.R.A., ON ART.*

WE are glad to see another edition of Sir EDWARD POYNTER's lectures. It shows how well they are appreciated by students, for to that class of readers they are mainly addressed. The production of lectures on art entails more of a sacrifice on the part of the author than is necessary in most classes of bookmaking. For an artist to set up as a public teacher is to impose rigorous laws on himself, unless he has the tact to keep clear of the branch of art which he practises. REYNOLDS was aware of that fact, and hence all he said about the power of MICHEL ANGELO or the admirable qualities of the CARRACCIS left his portraits unaffected. The late Lord LEIGHTON used to survey so vast a field of history it was difficult to follow him, and it would need unusual power on the part of a critic to find anything which could be applied in testing the *Daphnephoria* or the *Andromache*. LESLIE preferred to treat of Dutch pictures, but as he could not be said to have employed them for models, he also avoided the setting up a standard by which all could measure his delightful works. With Sir E. J. POYNTER, on the contrary, it is easy to see that, although he is not obtrusive of himself, he is constantly referring to his own practice and experience. Take one instance. As becomes an architect's son he loves architecture, and introduces it freely and accurately in his paintings. In his lectures students are advised to study the art earnestly. In one place he says:—"When we think of what infinite value architecture is in the composition of figures, it seems a shame that all painters should not possess a sufficient knowledge of it to draw it at least correctly, even if they do not aspire to designing it for themselves; as it is, I doubt if there be half a dozen figure painters in England at the present time who could introduce correctly a background of Classic or Gothic architecture into their pictures, much less design one. Therefore, I cannot indeed imagine a better preparation for a student of painting than that he should have been in an architect's office." When a painter has expressed an opinion so definitely, he is bound to be most careful in acting on it. The President is therefore precluded from introducing an architectural background unless it is as true in detail as an architect's drawing. If there is no example existing that will afford him evidence, he will have to labour at a creation until he arrives at something which will satisfy archaeologists. We may give another example of the self-imposed liens of the President. Occasionally he attempts landscape, and although opinions may differ about the degree in which nature is recalled in his drawings, it is generally agreed that the artist was painfully anxious to attain accuracy. No doubt Sir EDWARD POYNTER is an admirer of scenery, but, since he has lectured on art, he must testify by his examples that because he is a figure painter he is more qualified for landscape than those who make it a specialty. The best landscape painters of to-day are, he says, found among the figure painters, and he continues:—"A youth desirous of becoming a landscape painter cannot do better than study the drawing, painting and composition of figures; it will give him a power of drawing to be attained in no other way, besides cultivating his taste, his style, and his feeling for beauty of arrangement. The mere introduction which it gives him to the works of the great figure painters will be suggestive of a higher order of landscape than that which is gained by trivial and photographic studies of nature which pass for pictures among the younger school of landscape painters. . . . There is no such thing as teaching landscape painting. I cannot consent to consider it a separate art; teach a student to draw, and he will paint landscape or figures according as his inclination to one or the other dictates." We need not discuss how far the President's theory is correct. In France, where he was trained, young landscapists do not hesitate to work under figure painters. What we now contend for is that, as a supporter of the theory, the President is handicapped whenever he has an inclination towards landscape composition. Although he may only be occasionally moved to experiment, he is bound to demon-

strate his superiority to the specialists. It is no wonder critics observe, or imagine so, that Sir EDWARD POYNTER's later works exhibit too much self-consciousness, as if the artist were afraid of laying on his canvas a stroke that could be interpreted as spontaneous, or as not in accordance with the canons of art which can be derived from his lectures.

As he works under restrictions of his own making, the President has to be guarded in the view he takes of art as a whole. Sir EDWARD POYNTER objects to Mr. RUSKIN's theory of the close connection between morals and art, but, on the other hand, he does not appear to support the idea that art is one of the means devised by man to give himself pleasure. JAN STEEN is at the opposite pole to MICHEL ANGELO, but both subserve the same end. The works of each artist have admirers who find enjoyment before them. Neither the Dutchman nor the Florentine are satisfactory to Mr. RUSKIN, and many amateurs in the past as in the present would agree with him. It may be a proof of more refined taste to be able to appreciate the Sixtine figures, but educated men who are delighted with the homely village scenes of JAN STEEN do not as their knowledge increases grow disgusted with him and yield themselves to the supremacy of the painted Titans. But why should it be imperative to confine our admiration to either artist's works? It is surely allowable to consider the earth as more deserving of consideration than the men upon it, and if so representations of a part of the earth are no less justified than figure pieces as sources of pleasure. But, as we have said, the affording of pleasure seems to be an insufficient reason for the existence of a work of art with Sir EDWARD POYNTER, and accordingly he is severe on such innocent subjects as landscapes and flowers, as MICHEL ANGELO would have been.

That artist is brought forward in the lectures as a moralist as well as an artist. Sir EDWARD POYNTER says that one of the ways in which MICHEL ANGELO should be followed is by never condescending to catch applause by wilfully falsifying for fear that truth should be misunderstood. That suggestion inspires what is said about the economy of art. It is generally supposed to be the duty of a prominent artist to promote the sale of works by his contemporaries. The President would put restrictions on patronage. "No amount of what I may call almsgiving to art in the form of buying pictures (no matter how high the prices given) will ever change the poverty-stricken condition in which the larger portion of our community finds itself with regard to art." Elsewhere he says:—"It is well known that what some suppose to be an increasing love of art in this country, as shown by the high prices given for paintings, is now nothing more than a speculation in pictures; that the majority of buyers will not purchase unless they can 'buy safe,' as the saying is, which means that they do not buy pictures for the enjoyment to be derived from them, but in order to sell them again. If a certain pleasure in their acquisition enters into their calculations, it is just as likely to be a spirit of emulation in outdoing some other buyer as real pleasure derived from art; and even in this case they will not buy till they feel sure that they will not ultimately lose." It shows courage in an Academician to reveal that he does not wish to make a friend of Mammon, but there is still more courage needed in a President who dares to reprint words which run counter to the policy that was always followed in the Academy.

Yet it cannot be objected that the words are out of place. There is scarcely a subject which can be properly considered in relation to our time (religion, art, literature and politics are not exceptions) if the financial aspects are neglected. The practical character of the lectures is shown by what is affirmed concerning money as in other was. When Sir EDWARD POYNTER remarks, *à propos* of the showy vulgarities which pass for art, "It is, indeed, the dread of appearing not to be able to afford handsome things which is at the bottom of the general decline of good work which we find surrounding us on all sides; it is, combined with the desire of rapidly making fortunes, the root of all that is bad and sham in art about us," he points out the causes of evils which can be traced in most things. So general, indeed, is the prevalence of sham that many a designation in business, which at one time was honourable is fast becoming a synonym for an untruthful man, a suc-

* *Lectures on Art.* By Sir Edward J. Poynter, P.R.A., Director of the National Gallery; late Director for Art, Science and Art Department; late Slade Professor, University College. Fourth and enlarged edition. (Chapman & Hall, Limited.)

cessful deceiver. It is easy, therefore, to understand the laboriousness of Sir EDWARD POYNTER in treating the subjects of his pictures. To him apparently dexterity, sleight of hand and striking effects are allied to the evils which he denounces.

From his doctrine we must expect more or less austerity in the system of training which Sir EDWARD POYNTER proposes. His own style does not correspond with FORD MADOX BROWN's, but in what he says about the wall-paintings in the Manchester Town Hall we have a sort of abstract of what a student of painting who is sincere should aim at, and of what a zealous teacher should enforce. He says:—"I cannot conceive a finer lesson to students, young and old, than is conveyed by these paintings, whether we look to the thoughtfulness of the conception—going to the very heart of the subject in every case—to the fulness and variety of incident—to the vivid realisation of the treatment, or the care and interest shown in every part of the execution, or the originality of the decorative effect." No mention is made of beauty, but probably the ideals of the artist and his judge in this case would not correspond. By what process are the possession of qualities like those of the Manchester paintings to be attained? Sir EDWARD POYNTER is not afraid to recommend to beginners the copying of drawings in outline like those in DYCE's books, but as soon as possible outlines from solid objects should be attempted. Certainty and rapidity should mark all lines, and the use of indiarubber as leading to a bad habit should be avoided. The study of the figure must not be delayed, but at first casts of heads, hands and feet are preferable to full-length antique figures. Outlines are inadequate to express form in a thorough way, for, being deficient in light and shade, they can only give a conventional representation of an object. Next comes the study of tone, which, according to the President, generally is one of the weakest points of English pictures. He points out that "the perception of tone, in its extended sense, means the perception of that harmonious unity of effect, under every circumstance, which necessarily pervades all objects and scenes in nature, and the right application of those laws to compositions of form and colour; and it is impossible, unless a student is constantly directed to the acquisition of that perception, from the time when he begins by shading to give relief to his drawings, that he should ever afterwards be able to impart it to his pictures." One of the causes of the general deficiency in tone is said to be "the common habit of laborious work with the chalk point," and the stump is preferable. When drawing from life Sir EDWARD POYNTER recommends expedition, the French artists being exemplars of the skill and accuracy which are insured by never exceeding a prescribed time for their work. He would not have the student take up anatomy and colour too soon, and estimates that at least two years' regular work will be required before a student can draw the figure well enough to be unhampered by difficulties of proportion and construction. As regards colour, the President believes the first efforts of the student should be confined to the training which will enable him to see promptly and accurately the tones and colours of his model, for "if he is always painting colours which he does not see, with a view of correcting them afterwards by glazes and other methods, what probability is there that he will ever see colour truly?" The monochrome painting from casts in which the tone of the casts is disregarded, as practised in Government schools, is described as the most dangerous part of the Department's system. Insufficient as is our abstract it may help to suggest that in Sir EDWARD POYNTER's teaching veracity comes first, and a student who trusts his senses rather than his fancy, and who is industrious and painstaking, should have confidence of success. Of course natural ability is stipulated, for the present President does not anywhere adopt REYNOLDS's dictum that well directed labour is by itself ample to attain the highest elevations in art.

The book is so full of honesty, experience and insight, it cannot be too widely spread among schools of painting. It is also recommended for use in departmental schools, for Sir EDWARD POYNTER was probably the first artist who endeavoured to apply an effectual remedy to the evils of the system there followed. A great many artists accepted examinerships and other offices, but their tolerance only confirmed the principles which the permanent officials had

laid down. Sir EDWARD POYNTER, before he accepted office, protested against the malpractices, and when in office he insisted on the adoption of some remedies. That he was not able to do more testifies to the strength of departmental conservatism.

CONCILIATION AND STRIKES.

WHENEVER strikes become inconvenient to the public complaints are raised by would-be economists because "Conseils de Prud'hommes" are not comprised among English institutions. The history of some of the late strikes in France has demonstrated that there are contests between employers and employed in which the Conseils are about as effective in settling differences as would be a troop of babies from a *crèche*. The latter might appeal to the emotions of strikers, whilst the Prud'hommes would be considered in the way, especially if trade interests had been conjoined with political rancour. There are cases in which the Conseils become useful, but probably they will not be as successful for many years as they were half a century ago. Although unknown in Paris until 1844 the institution has existed since 1806, when it was organised in Lyons—a city that was long familiar with labour disputes. The duties of the members are not confined to the settlement of differences by conciliatory speech. Recalcitrant apprentices can be fined or sent to prison for three days by a Conseil, workmen who disturb ateliers can also be punished, and there is power for dealing with trade marks within prescribed limits. The establishment of the tribunals was, however, a concession to the French workman. Prior to the Revolution he could hardly be considered as entirely a free labourer. LOUIS XIV., when he resolved to set up Dr. PERRAULT's colonnade at the Louvre, put forth an edict prohibiting the employment of masons and stone-cutters in Paris until the royal superintendents had selected a sufficient number for the works, and any workman who asserted his liberty by withdrawing was liable to be sent to the galleys. His Majesty was always gracious to his nobles and was ready to share his privileges with them, so there would probably be little difficulty in compelling a number of men to abide near a château or one of its dependencies until the completion of the works. Instead of summary punishment, the Conseils de Prud'hommes used persuasion, and, what was more important, some of the judges were workmen and could exhibit a fellow-feeling with one of the parties in the dispute without much risk to their impartiality.

The Conciliation Act, which became law in England a year ago (August 7, 1896), has introduced a principle which is analogous to that of the French Conseils. It is intended to encourage and extend the work of voluntary conciliation boards, and to settle, under certain conditions, actual disputes between employers and workmen. The Board of Trade is the chief agent in carrying out the conditions of the Act. It has power to inquire into the cause of any difference which may arise among different classes of workmen or between employers and employés. Arrangements can also be made by the Board for a meeting between the disputants or their representatives under the presidency of a selected chairman. The Board can likewise, on application of the parties, appoint a conciliator or board of conciliation and also an arbitrator. In most of these arrangements the initiative does not belong to the Board of Trade, and it cannot be objected, therefore, that Government is eager to meddle with private affairs and has passed the Act to obtain facilities.

So many social experiments which are sanctioned by Acts of Parliament and directed from Government offices have been slowly accomplished, it is not to be expected that the industrial world will at once accept conciliation boards as the most effectual remedy to cure the troubles of trade. For a time practical people will necessarily be sceptical about the advantage of any machinery which circumlocutionism has created. But it must be allowed that the first year's experiments with the Act have been more encouraging than was anticipated. Thirty-five cases have gone through the official process. In four of them the Board did not seek permission to act, but in the remaining cases the parties concerned were desirous to be subjected to treatment. Out of the thirty-five only four were

found to be too refractory for a settlement, and the result in one case was not determined. There is no doubt that if the failures are few it is owing to the tact shown by Sir COURTENAY BOYLE. The part taken by him in the correspondence with Lord PENRHYN respecting the slate quarries was not that usually adopted by a high Government official. He did not appear to suggest that the Whitehall lightning was controlled by him, and that he could be dangerous. Sir COURTENAY BOYLE preferred to appeal to his lordship's humanity, and if the three thousand unfortunate quarrymen are still in misery the responsibility does not rest with the Board of Trade. It may be said, in passing, that no trade dispute presented a more ridiculous side, for it will be remembered that after a long course of diplomacy the negotiations collapsed because there was not a quarryman who was a competent shorthand writer. The incident will, of course, be utilised by advocates of the new systems of education. It is right to "find quarrel in a straw where honour's at the stake," but to inflict suffering on a crowd of unoffending women and children because none of their relatives is a stenographer is one of the strange actions which make foreigners believe that "the insane root which takes the reason prisoner" is a favourite article of diet in England. After the Welsh experience, who can any longer doubt the impossible tasks set by the terrible giants of the nursery legends?

Among the thirty-five disputes seven belong to "building and kindred trades." In one the Board declined to interfere. Two were settled by conciliation and one by arbitration. In two cases there was no settlement effected, and one is pending. The official mind must be disturbed by the exhibition of perversity which is occasionally offered. The master painters in Middlesbrough, for example, agreed to the Board's terms of arbitration, but the men declined. Then the men changed their resolve, but the masters had also changed, and were not to be moved to share in a conference. As long as a game of see-saw of that sort gives satisfaction there is not much chance for conciliating. The bricklayers and plasterers of Newcastle spent about four months in a similar game, then private mediation brought it to a close. The combined efforts of Mr. W. E. WILLINK and a Board of Trade officer succeeded in ending a dispute of the Prescott carpenters and joiners. In the Potteries the case was somewhat complicated, but Sir WILLIAM MARKBY was enabled to arrive at an agreement. The carpenters and joiners asked for an advance from 8*d.* to 9*d.* an hour. The employers claimed a reduction from 8*d.* to 7*d.*, and also sought for a change in the form of indentures, on the ground that, while bound to retain their apprentices when work is slack and journeymen are discharged, the relative proportion of the two classes becomes altered, and the employers can be charged with a breach of the working rules. The men agreed to add to the rule the following addition:—"Any builder having more apprentices than are authorised owing to the dismissal of journeymen through slackness of trade, will not be allowed to take on any more apprentices until the number has been reduced below the standard set forth." The men's demand for an increase of wages was arranged by giving them 8½*d.* an hour, and it was held there was no ground for the masters' proposed reduction. An arbitrator in such cases requires to be firm as well as discreet, and, above all, he must have a reputation for impartiality. As Sir COURTENAY BOYLE says, the Board of Trade will have to rely more and more on the aid of such gentlemen as Sir WILLIAM MARKBY, Sir DAVID DALE, Sir HORATIO LLOYD, Captain WILSON, Mr. THOMAS BELL, Mr. WILLINK, Mr. BAILLIE DUN in completing negotiations which in the preliminary stages were conducted by officers of the Board of Trade.

The attempts which were successful were mostly in contests where the parties engaged were not numerous. The Penrhyn dispute remains unsettled. But a still greater struggle is now in progress. The engineering strike, in which from 40,000 to 50,000 men are engaged, affords a test of the efficacy of the Conciliation Act which we trust will not often be equalled and never surpassed. So wealthy a trades society as the Amalgamated Engineers at first may not be disposed to listen to the counsels of the representatives of the Board of Trade; but every one who has any concern for British prosperity must wish that reason, although appearing in an official guise, will sooner or later succeed.

DANGERS CONNECTED WITH THE SUPPLY OF ELECTRICITY.

THE committee appointed by the Home Office have recently presented their report on this matter, having inspected twenty-six generating and sub-stations in various parts of the United Kingdom. Owing to the technical nature of the matter the committee have had the assistance of several experts. In the report it is stated that the committee have been in consultation with the Board of Trade in order that there should be no division of authority between that Department and the Home Office.

The report commences by describing the different systems of generating and distributing electrical energy from supply works. The uses of some of the apparatus are mentioned, and the dangers of working are then gone into, some of which it may be well to mention here.

In connection with accumulators there is a risk in their use in consequence of the evolution of an explosive mixture of gases when the plates are overcharged. Where the ventilation is very imperfect the quantity of gas may accumulate sufficiently to take fire or explode on contact with a spark or flame.

The danger peculiar to electrical generating works is the liability to shock, which is often fatal if, by accident or carelessness, anyone comes into contact with the conductors when charged to a high pressure. The contact need neither be very perfect nor direct, provided two parts of the body are made to touch conducting materials which themselves differ in pressure by 1,000 volts or more, or even by much less; if the contact with the flesh is very good, a dangerous and possibly fatal shock will result.

In connection with this, it may be noted that of the fourteen fatal accidents which have occurred in the last five years, in not one case was the pressure below 1,000 volts.

The metal which is highly charged, and which would be liable to be touched if not properly protected, is to be found in the dynamo machines, the switchboard and its metal connections, the high-pressure mains and the transformers, and, in the case of series arc lighting, in the lamps themselves.

In the case of high-pressure alternators or dynamos it should be impossible for the attendant whilst oiling the bearings or cleaning the frame to make contact with any live metal. Efficient guards should be arranged over the collectors or commutators, terminals and leads for this purpose. Oil-cans with insulating handles, we think, are not commendable, as the fingers may be placed thoughtlessly on the metal portion to steady it, and if all live metal is well guarded and the frame earthed an insulated oil can is unnecessary. It is the custom now in well-designed high-tension switchboards to so protect the live metal-work in the front that it is impossible for the attendant's hands to come into contact therewith when operating the switches.

The switchboard should be easily and quickly accessible on the front, where all the ordinary operations of connecting and disconnecting the various dynamo machines and cables are effected. The back should be inaccessible except to those skilled persons who have the right and means of entry.

This latter is a very necessary precaution, as it is often possible to touch live portions of metal and iron supports or stays which are practically earthed, and a person who is not fully aware of such danger should have no access to such places.

There is no necessity for any metal directly connected with the high-pressure mains of dynamos to be exposed on the front or working face of the switchboard to accidental contact.

High-pressure main conductors may be erected as overhead wires, but are almost universally laid under ground. Bare overhead high-pressure conductors may lead to accident in case of breakage or by swinging into contact with buildings, &c., under the action of the wind, or by earthing at the points of support in consequence of damage to the insulators. High-pressure overhead wires, even if insulated over their entire length, can never be considered as entirely free from risk. In underground cables the insulation which is employed to prevent loss of current will, when it is perfect, *i.e.* undamaged, amply protect anyone touching it from any dangerous pressure from the metal within, but an injury which would not be sufficient to be

detected in ordinary working might nevertheless allow of the escape of sufficient current to produce instantaneous death.

Arc lights, when supplied with current from a central station, are usually arranged in series, *i.e.* the same current is sent through a number of lamps. As an arc lamp requires an electrical pressure of from 40 to 50 volts, dangerous pressure becomes necessary when several lamps are arranged in series, for the electrical pressure is the sum of the electrical pressures of all the lamps separately. In consequence of the fact that these lamps can in many cases only be reached by means of a ladder, a shock, harmless in itself, may cause a man to lose his hold and be seriously injured.

The following are abstracts of some of the recommendations contained in the report. A station where the direct current generated is at or above 700 volts, or where the alternating current is at or above 350 volts, shall be considered a "high-pressure station." We fail to see any reason for such a difference between alternating and continuous current.

The floors of all places where it would be possible to make connection with metals at high pressure shall be covered with an insulating mat of suitable material, and kept in a state of efficient insulation. In switch-rooms and on the front of switchboards, the main switches, main fuses, main terminals, omnibus bars and all other metallic parts shall be insulated or arranged in such manner as to render it impossible for any person by accident or inadvertence to touch them.

The backs of all switchboards shall be kept closed, except for the purpose of alterations and repairs. When such work has to be carried on either at the back or at the front of switchboards the following regulations shall apply:—

(a) No person except a skilled electrician or a workman under his personal and immediate supervision shall be employed when any part is at high pressure.

(b) No extensive or serious repairs shall be executed upon metal which is at high pressure.

(c) Where the alterations or repairs are not of an extensive or serious character, all metallic parts at high pressure shall be covered by an insulating cap or protected by some form of insulating covering, only one part, or several at the same pressure, to be exposed at any one time.

All switchboards erected after the application of these rules shall have at the back a clear space of at least 4 feet. This space shall not be utilised as a store-room or lumber-room, or be obstructed in any manner. This latter precaution is very necessary, as such places are frequently kept in a very bad condition, being often filled with old timber, repairing material, or left in an unfinished condition.

Any person at work upon a cable or portion of the mains under high pressure shall wear indiarubber gloves on both hands.

All aerial high-pressure conductors in factories or workshops shall either be insulated over their entire length, and supported at such frequent intervals that, in the event of breakage, they shall not come within reach at places where persons are liable to pass or to be employed, or shall be so placed and arranged as to comply with requirements relating to such wires in streets, enjoined by the Board of Trade.

No examinations, repairs or alterations necessitating the handling of mains, wires, machines or other apparatus shall be carried on except in cases of urgent necessity while such parts are under high pressure, and all such work shall be done under the personal supervision of an electrical engineer or competent manager or foreman. This is a rule that may sometimes be found irksome, but is highly necessary on high-pressure installations.

Switches that can be conveniently operated from the outside for cutting off both the high and low-pressure connections of the transformers shall be fitted in all transformer chambers erected after the application of these rules, and in all existing chambers, unless it is proved to the satisfaction of Her Majesty's Chief Inspector of Factories that such an arrangement would be attended by special difficulty.

This will apply to existing transformer chambers, and will be an important additional safeguard in places where live portions of metal are situate near the inlet to the chamber.

Each post or support where series arc lighting is employed shall be provided with means for completely disconnecting the arc lamps from the mains without disturbing the action of the other lamps.

This would entirely obviate the danger before mentioned, where a ladder is used for attending to the lamps, and it should be made compulsory for the men to use these switches whether the mains be alive or not, as there would then be less liability of their forgetting them.

The majority of the committee's recommendations are practical and necessary, and will accord with the ideas of those who have the control of central stations, but if adopted as they stand will greatly increase the responsibility of the chief officials in such works. For instance, for the manager to see that rubber gloves are worn by workmen when employed on high-pressure mains would be practically impossible. Also for all persons employed in the works to be made acquainted with the dangerous parts of machinery, &c. seems unnecessary, as the men connected with the boiler-house should not have access to the engine or switch-room.

Most of the accidents which have occurred in electric supply undertakings have been due to carelessness or breach of the regulations. There are dangers with all machinery if reasonable care is not taken, and not only with machinery in connection with electric supply.

THE CHANTREY BEQUEST.

THE following letter, signed "L. G. R.," on the administration of the National Gallery of British Art, especially in dealing with the pictures purchased under the Chantrey bequest, appeared in the *Times* on Monday:—

The Tate Gallery having now been formally opened and handed over to that vague entity "the nation," it is of importance to know the actual position of the various bodies officially represented at the inaugural ceremony. Mr. Tate, in his short speech, stated "the Government had promised to maintain the gallery, and the trustees of the National Gallery have undertaken the management of it." The direct appointment of the keeper, Mr. Charles Holroyd, by the Treasury—as officially announced—would seem to suggest that the rôle of the trustees is somewhat effaced. On the other hand, what are we to understand by the maintenance of the Tate Gallery? The keeper and his subordinates will need to be paid, and provision for their salaries must be made by Parliament. As the completion of the Tate Gallery during the present summer could have been well foreseen, the amount required might have been included in the ordinary estimates for the year, whereas now it will be hurriedly voted in the supplementary estimates just presented, which in all probability will be pushed through without discussion.

This is to be regretted, for the public really need to hear a good deal more about the Tate Gallery than has yet been revealed. All that is known is that a private benefactor has, at a large expense, erected a gallery far in excess of the requirements of his special gift, and that in the building thus obtained at no outlay of public money certain pictures belonging to the nation and others are hung. For many years, as is well known, the Trustees of the National Gallery have been clamouring (in a minor key) for more space and for an extension of their present building. To these appeals the Treasury has turned a deaf ear, vouchsafing no explanation of its policy. Suddenly we are told that Mr. Tate's Gallery is to receive from Trafalgar Square the pictures (with a few exceptions) by British artists born since 1790, and Mr. Tate himself tells us that he proposes to "utilise the remainder of the land granted by the Government" for an extension of the present gallery. This can only mean that there will sooner or later be a further removal of pictures by British artists from the National Gallery and the South Kensington Museum, and that by this means the demands of the trustees of the former for further space will be indirectly satisfied out of Mr. Tate's pocket. Since the completion of that monument of national meanness (and private generosity), the National Portrait Gallery, the attitude of the State towards art has never been displayed in clearer colours.

With the Watts pictures it is scarcely necessary to deal, the donor being still alive and able to make such conditions as he may consider expedient. It is very different with the Chantrey pictures, and the appearance of the Royal Academicians in a quasi-official character at the opening of the Tate Gallery was at least strange. Without having the exact wording of the bequest before one it would be dangerous to speak too positively, but no one who has read Sir Francis Chantrey's biography or his letters, as published after his death, can doubt that his double intention in providing the means for purchasing the best

29. Waiting-room for the public, connected with the reception hall above specified.

30. Room for pages near that of the serjeant-at-arms.
 31. Hall of Sessions of the Chamber of Senators for fifty members. Attention should be paid to the directions which have already been given in relation to the Chamber of Deputies concerning the required rooms, their arrangement, lighting and ventilation, modifying the proportions according to the difference in capacity of the two Chambers.
 32. Private study of the President of the Senate, with reception-room and toilet.
 33. Workroom for four stenographers, with ready access to the Hall of Sessions.
 34. Cloak-room for the senators.
 35. Room where the senators can write.
 36. Wash-room and water-closets.
 37. Office for the serjeant-at-arms of the Senate.
 38. Waiting-room for the public, connecting with the general reception hall, previously specified.
 39. Room for pages, near that of the serjeant-at-arms.
 40. Offices of the Supreme Court (Contaduria Mayor de Hacienda), comprising private office for the chief clerk, room for sixty employés, office for the sheriff or marshal, room for utensils, toilet-room and water-closets.
 41. Office of the director of the Journal of the Debates.
 42. Office of the treasurer of the Congress.
 43. Office of the chief secretary of the Chamber of Deputies. This room must be in direct communication with the room for employés, and must be preceded by an ante-room.
 44. Workroom for thirty employés of the secretary's office.
 45. Fireproof storage-room for the archives of the Chamber, communicating with the room just mentioned.
 46. Four rooms for the Commission of the Chamber of Deputies (five persons), two larger rooms for joint commissions (twelve persons), and a room for the grand jury (thirty persons).
 47. Library and reading-room for the deputies and senators.
 48. Office of the librarian.
 49. Room for office utensils for the Chamber of Deputies.
 50. Room for the sorting and distribution of documents.
 51. Workroom for journalists in direct communication with their gallery.
 52. Office of the chief secretary of the Chamber of Senators, to have ante-room, and to be in direct communication with the room for employés.
 53. Workroom for twenty employés of the secretary's office.
 54. Three rooms for commissions of the Senate; one for joint commissions; a room for the grand jury.
 55. Fireproof-room for the archives of the Chamber, communicating with the secretary's offices.
 56. Room for utensils and materials for the Senate.
 57. Room for sorting and distributing documents.
 58. Toilet-rooms and water-closets at such places as may be deemed necessary.
 59. Restaurant for the two Chambers, with smoking-room and reading-room for periodicals.
- Besides the rooms specified above, candidates may add such as their study of the subject suggests as useful or necessary to the purposes of the edifice. The communications between the rooms pertaining to the two Chambers must be convenient, and corridors and stairs must be spacious and well lighted.

Drawings and Specifications.

The following drawings must be presented :—

Plans of the foundations, with indications of the various loads.

Plans of each storey, with indication of the purpose of rooms comprised in it.

Elevation of each front, with a profile, to show the projections.

Sections suitably chosen to give an idea of the interior proportions of the building in its principal parts.

All these drawings must be prepared at the scale of 1:200.

Detailed drawings of the two Halls of Session, showing the arrangement of the seats, must also be presented, as well as detailed drawings of the grand vestibule and the main reception hall. These drawings must be at a scale of 1:50.

A perspective view may also be sent, and detailed drawings of the ornamentation. The detailed drawings may be simply sketched, but in such a way as to show clearly the ideas of the author. A list of the drawings sent must accompany them.

The drawings must be accompanied by an explanatory specification, written in Spanish, French or English, and comprising a general description, as well as an account of the arrangement of the building, a specification of the materials to be employed in each of its parts and an estimate of the cost, as closely approximate as possible, using as far as may be the list of prices annexed to this programme. The total cost must not exceed 1,500,000 dollars, without counting the cost of the foundations to the level of the street.

In order that the designs may be fairly judged it is absolutely necessary that the candidates should conform to the conditions above specified.

The drawings and specification must bear a mark, which is to be repeated on the outside of a sealed envelope, in which is to be found a paper containing the name of the author of the design, his address and other information sufficient to establish his identity. Meanwhile, candidates should give an address

which will permit of making known to them the decisions which may be taken in regard to the competition.

The designs must be sent by the candidates to the Ministry of Communications and Public Works, either directly or through the diplomatic or consular representatives of Mexico in foreign countries, on or before November 30, 1897. After that date no design will be admitted to the competition.

Jury.

The designs will be submitted to the examination of a jury, which will make the awards. This jury will be composed of seven architects or civil engineers, appointed, one by the Chamber of Deputies, one by the Senate, one by the Ministry of Communications and Public Works, and four by the candidates, by means of a written ballot, from among ten experts proposed by the Ministry of Public Works. They must not be participants in the competition and will be chosen by the absolute majority of ballots.

For this purpose the candidates must send with their drawings and specification a list containing the four names of the persons whom they choose as members of the jury. Before the making of the award, the *Official Journal* of the Government of the Mexican Republic will publish the result of the ballot held for the formation of the jury, over which the Minister of Public Works or his representative will preside.

Prizes.

The author of the design placed first will be entitled to a prize of 15,000 dols. in Mexican silver, of which he will receive one-half at once, and must complete his design, furnishing all the detailed plans for execution, in such a manner that his ideas may be faithfully interpreted.

As soon as he delivers these plans he will receive the other half of the prize above specified. The designs classed second and third will receive together a prize of 6,000 Mexican dollars, divided in a proportion which will be determined by the Jury of Award. Finally, the designs classed fourth and fifth will receive respectively a gold and a silver medal, with a diploma of which the form and the inscriptions will be determined by the jury, and, in addition, 500 Mexican dollars each, as a contribution to the cost of making them. The designs classed first, second and third will become the property of the Mexican Government.

The designs submitted in competition will be exhibited for ten days after the award is made, at such place as may be designated by the Ministry of Communications and Public Works.

The decision of the Jury of Award will be published in the *Official Journal* of the Federal Government.

Four months after the publication of the result of the competition the designs not awarded prizes must be withdrawn; and if they are not so withdrawn they shall become the property of the Mexican Government.

No candidate shall make known his name in advance, under penalty of exclusion from the competition.

The sealed envelopes relating to designs not accepted will not be opened, and will be returned to their authors, with the drawings and specifications to which they belong, on presentation of the receipt given for them.

THE BROOK HOSPITAL.

AT the meeting of the Metropolitan Asylums Board on July 31 the Brook Hospital committee presented a statement of the final accounts submitted by the architect of the cost of the erection of the Brook Hospital. These showed the total cost, including purchase of site, equipment, &c., to be approximately 319,241*l.* 16*s.* 3*d.* The expenditure on the buildings was 268,623*l.* 4*s.*, which sum exceeded by 64,000*l.* the amount of the estimates presented to the Board, and was in excess of the actual amounts of the various contracts entered into by the sum of 50,000*l.* The committee recommended that the final accounts and reports of the architect be referred to the clerk to the Board to report to the managers upon their legal position in regard to a paragraph entitled "claims" in the architect's first report, with power to the clerk to employ legal assistance; and, further, that application should be made to the Local Government Board for an order authorising a further expenditure on loan in respect of the erection, equipment, &c., of the Brook Hospital of the sum of 100,000*l.*, in lieu of the sum of 75,000*l.* applied for in October, 1896. Mr. J. Brown, chairman of the committee, in moving the adoption of the report, pointed out that a very large amount of additional work had been executed, and that the three building contractors had each made extra claims, amounting to 9,850*l.*, beyond the ordinary accounts, principally in respect of the delay caused by the alteration of the drainage outfall, which practically stopped all useful progress of the works for over six months. On the motion of Mr. G. S. Elliott, the debate was adjourned until October 30. In the meantime it was resolved to apply to the Local Government Board for an order authorising the additional expenditure

NOTES AND COMMENTS.

THE Council of the Whitworth Institute, Manchester, have expended the whole of the large donation of the guarantors of the Jubilee Exhibition of 1887, with the exception of the small sum of 14 os. 8d. At such a juncture it has been fortunate to receive from Mr. DARBISHIRE 10,500 shares in Sir W. G. ARMSTRONG, WHITWORTH & CO., LIMITED, which are now worth 27,000*l.*, and from which satisfactory dividends are expected. The Council being therefore more secure about the future have decided to erect a third gallery, corresponding in position and dimensions with the North Gallery, and, like it, accessible from the Central Gallery, with an extension of the temporary corridor alongside of the old house. As this new gallery will front the park, it is proposed to construct, with material removed from the new foundations, a handsome terrace, which will at once add dignity to the edifice and provide a fine promenade walk overlooking the park towards the south. The erection of the new building will be carried out, as have been the existing galleries, under the direction of Mr. J. W. BEAUMONT, by Messrs. NEILL & SONS. During the past year the Council were presented with the following oil-paintings:—*Interior of the Prison of Chillon* (an early work of CLARKSON STANFIELD, R.A.), given by the executors of the late Mrs. B. LIEBERT; *Temple of Jupiter* (J. M. W. TURNER, R.A.); *Springtime and Autumn Sunset* (J. T. LINNELL), given by Miss HEAVEN; and *View of Rome from the Barbarini Gardens* (D. ROBERTS, R.A.); *Cittara, Gulf of Salerno, and Oude Scheld, Texel Island* (C. STANFIELD, R.A.); and *The Emigrants and A Roadside Nibble* (JOHN LINNELL), given by Mr. DARBISHIRE "in memory of the late Sir JOSEPH WHITWORTH," out of funds bequeathed by him.

THE late ERNEST RENAN was born at Tréguier, in Brittany, and many of his most delightful pages are inspired by the primitive place and its inhabitants. It is only right that some memorial of so eminent a man should appear in his birthplace. Originally intended for the priesthood, he was led by his devotion to the study of Hebrew and other Semitic literature to abandon a belief in Christianity. But, unlike most perverts, he always wrote in affectionate terms about the faith in which he was instructed by his mother, and he once went so far as to say that if his condition of mind were realised, the proper place for his tomb would be in a cloister attached to the old church of Tréguier. That suggestion is now utilised by the local authorities as a means to obtain possession of the cloister. As a part of the church, it is supposed to be ill adapted for a memorial or monument of RENAN, but as a secular structure it would, they say, be most suitable. The Municipality do not, however, propose to go to the expense of a monument. It is not considered that RENAN was no vandal, and if he could have anticipated the move of the councillors he would have expressed opposition to their proposal.

THERE was lately issued from the Foreign Office a report on iron and steel bridges in Egypt, in which the practice of British contractors was contrasted with German practice, and the latter was extolled. It is not to be expected that Lord CROMER, the author of the report, should be acquainted with the designing and construction of bridges, but a little knowledge would have given another character to his lordship's report. In 1894 some very prominent firms, viz. HEAD, WRIGHTSON & CO. (LIMITED), the HORSELEY COMPANY (LIMITED), JOSEPH WESTWOOD & CO. (LIMITED), the HORSEHAY COMPANY (LIMITED), ANDREW HANDYSIDE & CO. (LIMITED), P. & W. MACLELLAN (LIMITED) and Sir W. ARROL & CO. (LIMITED) were compelled to protest against the system adopted by the Egyptian Railway Administration. Practically neither drawings nor specifications are supplied which are sufficient to enable a contractor to tender in a legitimate way. The drawings for two larger bridges across the Nile were described as simply sketches showing the positions of the proposed bridges, giving no information beyond the total length of the bridge, the number of spans, the rail level, the position of the swing openings and the bed of the river; whilst the specifications gave but the barest details of the requirements of the Board, such as gauge of road, width of trainway,

footpaths, rolling load, breaking strains of iron or steel used and other very general elementary particulars. It therefore followed that contractors have not only to submit prices, but have also to prepare and submit designs. An English contractor from his innate honesty and fidelity to procedure hesitates to prepare designs, because with us the engineer is considered to be the sole judge of the amount of material which it is necessary to use and its disposition. Out of eagerness to secure work there is a risk that a go-ahead contractor will reduce the margin of safety to a minimum, and apparently there are bridges in Egypt which may be pointed to as victories of Italian, French and German contractors over Englishmen, but how long they will endure is not certain. All the English contractors desired was that competitors, of whatever nationality, should be placed on the same footing by the Egyptian Government, having the whole design in detail prepared by its own or some independent engineer, with full and proper specifications, as is done by the Indian, Colonial and other Governments, also by English and foreign railways and other public and private bodies. Great as is Lord CROMER's influence in Egypt, it was either not exercised or was not successful in attaining that end. As long as the Egyptian Railway Administration is satisfied with evading the responsibility which is usual, it is more creditable to British contractors to allow work to escape from them than to have their names associated with unstable bridges.

ILLUSTRATIONS.

THE NATIONAL GALLERY OF BRITISH ART, MILLBANK, S.W.
VIEW FROM SOUTH CORNER.—VIEW LOOKING ACROSS DOME.

THE new gallery at Millbank will be opened to the public on the 16th inst. The appearance of the place suggests a new settlement in the wilderness of London, but when the approaches are completed, the new bridge over the river constructed and workmen's houses set up, the site will present a different sort of aspect. Mr. SIDNEY SMITH has provided an octagonal gallery for sculpture, but we cannot expect to see it adorned with statuary until some years elapse. There are seven picture galleries, three being 59 feet by 32 feet, and a long gallery of 93 feet by 32 feet. There are also two special octagon galleries, one of them being occupied with several of the works of Mr. G. F. WATTS. The two at his desire are painted red, the other picture galleries are more of a plum colour. The following inscription is found on one of the pillars in the central hall:—"This gallery and sixty-five pictures were presented to the nation by HENRY TATE for the encouragement and development of British art, and as a thankoffering for a prosperous business career of sixty years."

CATHEDRAL SERIES.—CANTERBURY: SECTION OF NAVE & AISLES AT THE WEST END, WITH ELEVATION OF THE TWO TOWERS.—SECTION OF SOUTH TRANSEPT AND PART OF TOWER.—ELEVATION OF NORTH TRANSEPT AND PART OF TOWER.—SECTION OF NORTH SMALL TRANSEPT.—ELEVATION OF THE WEST SIDE OF SOUTH TRANSEPT, ETC.—SECTION OF CRYPTS, TRINITY CHAPEL, BECKET'S CROWN, ETC.

THE sections by TAYLOR & CRESY, which we reproduce, were praised by Professor WILLIS for their accuracy. The difficulty of measuring so large a building is manifest. The drawings are also a record of the state of the building about 1820. For example, the north-western tower is shown in its original form when it exemplified the Norman style alone. The sections do not need further explanation, with the exception of one through the crypts and eastern part, where the following explanation of the letters of reference will be useful:—

a. Section of the small column in the centre of the crypt, with a profile of its capital *a* and base *d*; *b*. Larger column, with profile of the capital; *c*. Profile of base of ditto; *e*. Small column in the middle part of the crypt, with its arch mouldings and great pier beyond; *f*. Screen and entrance doorway to the Virgin Chapel; *g*. Upper part, or parapet, of Becket's Crown; *h*. North end of eastern transept, with timber-work of roof; *i*. A vaulted room between the floor of the west end of the Trinity Chapel and the circular aisle of the large crypt. Two compartments of the screen on the north side of the altar, between that and the aisle, are shown.

THE WALLACE COLLECTION.

BY a Treasury minute, dated May 3, 1897, it was recommended that a small committee should be appointed to inquire and report where, in what manner and at what probable cost provision may best be made for the housing and exhibition of the art collection recently bequeathed to the nation by Lady Wallace, and to make any recommendations that may seem fit to them as to the constitution of the trust in which the collection should be vested.

It was also suggested that the constitution of the committee should be as follows:—

The Right Hon. the Marquis of Lansdowne, K.G., G.C.M.G., C.G.S.I. (chairman), the Right Hon. Sir William G. Vernon Harcourt, M.P., Sir Edward J. Poynter, P.R.A., Mr. Algernon Bertram Freeman Mitford, C.B., Sir Francis Mowatt, K.C.B., Mr. Walter Armstrong, director of the National Gallery of Ireland, Mr. Alfred de Rothschild, Mr. Alfred Waterhouse, R.A., LL.D., with Mr. Charles G. E. Welby as secretary.

The following report is submitted by them:—

The committee appointed under the Treasury minute of May 3, 1897, to inquire "where, in what manner and at what probable cost provision may best be made for the housing and exhibition of the art collection recently bequeathed to the nation by Lady Wallace, and to make any recommendations that may seem fit to them as to the constitution of the trust in which the collection should be vested," beg to submit the following report:—

1. The conditions upon which the Hertford House collection was bequeathed to the nation by the late Lady Wallace are as follows:—

a. That Her Majesty's Government shall agree to give a site and build thereon a special museum.

b. That this site shall be in a central part of London.

c. That the museum shall be a "special museum," and that the collection "shall always be kept together, unmixed with other objects of art."

2. The following proposals for disposing of the collection were considered by us:—

(i.) To retain it at Hertford House.

(ii.) To remove it to a building adjoining, or in the neighbourhood of, the National Gallery.

(iii.) To remove it to a new building to be erected upon an independent and suitable site.

(iv.) To remove it to South Kensington.

We consider ourselves bound to make no recommendations but such as shall amply comply not only with the letter but with the spirit of the bequest.

We are of opinion that (iv.) would not be in accordance with the conditions of the bequest, and must therefore be dismissed from consideration, that both (i.) and (ii.) would comply with the provisions of the bequest in regard to centrality, and that although the retention of the collection at Hertford House might not involve the actual construction of a special museum, it would nevertheless sufficiently comply with the terms of the bequest, and be strictly in accordance with the intention of the testatrix. The opinion of the law officers of the Crown and the evidence of Mr. Murray Scott are distinct upon these points.

We now proceed to express our views on the merits of the three alternatives before us.

Hertford House.

3. So long as the Wallace collection was private property it could probably not have been exhibited in a more attractive or appropriate manner than that in which it has been dealt with at Hertford House. The combination of admirable pictures with objects of art of many different kinds, all of the highest order of excellence, and the arrangement of these throughout the different apartments and reception-rooms, as well as in the exhibition galleries, have been carried out with the greatest skill and taste. It would have been impossible to display the collection in a manner more calculated to illustrate the knowledge and discrimination of those by whom it was brought together.

Of the pictures hung in the reception-rooms and private apartments, some no doubt pay the penalty to which works of art belonging to private collections are often subject and are indifferently lit. The picture galleries, on the contrary, are lit from the top, and the pictures are seen to advantage, although it would be possible even here to improve the lighting.

The whole collection, however, suffers from overcrowding. This is the case even in the picture galleries, where the space between one picture and another is insufficient for their proper display. The china, miniatures, snuff-boxes and other articles of *virtu* require more space before they can be seen properly. The large quantity of furniture now in the house would also interfere to some extent with the convenience of visitors if the premises were used as they stand for the purposes of public exhibition.

4. These drawbacks could, however, be overcome.

It is in the first place to be borne in mind that, under the terms of the bequest, "personal and modern jewellery, trinkets and effects," as well as "ordinary modern furniture and chattels," do not pass to the nation. Whatever interpretation may be given to these words, it is clear that a large number of pieces of furniture, many of them very bulky (*e.g.* beds, sofas, fauteuils, a billiard table, &c.), would not remain in Hertford House should it be acquired by the public. The relief thus afforded to the remainder of the collection would be material, and the removal of some of the larger pieces of furniture which now encroach on the wall space would add considerably to the space available for the display of pictures.

5. The evidence we have received goes to show that, were Hertford House made use of as a museum instead of for residential purposes, the amount of space available for the display of the collections could be further increased, and could be made amply sufficient for the purpose.

It has been suggested to us that with this object the space on the ground floor to the north and west of the courtyard, now occupied by stables, coach-houses, &c., could be appropriated for new exhibition galleries. These would not have any top light, but could be well lit from both sides by windows opening into George Street, into Manchester Street, and into the central courtyard. They would largely increase the available space, and would be well suited for the exhibition of objects of art of all kinds. Mr. Taylor, in his evidence, estimates that this alteration would increase the floor space available for exhibition purposes by about 7,000 square feet, thus increasing the total available floor space from some 18,000 to some 25,000 square feet.

It has also been suggested that the length of the picture galleries on the first floor could be increased by extending the skylights, thus converting the first floors of the eastern and western wings of the main building into exhibition galleries lit from above. This would involve the removal of those rooms on the second floor which are immediately above the rooms in question.

It would be for consideration whether the armour should not be removed from the top-lighted galleries which it now occupies upon the first floor, its place being taken by a part of the collection of pictures.

We believe that the adoption of these suggestions, or some of them, together with minor alterations which we do not think it necessary to specify in detail, would enable the collection to be worthily exhibited, and would afford ample room for ordinary visitors, although it is possible that when the collection is first thrown open an exceptional number of visitors might be attracted, in which case special restrictions would have to be imposed for a time. Should it be thought necessary to provide means of egress other than those afforded by the main entrance in Manchester Square, additional exits could, without difficulty, be contrived on the eastern and western as well as the northern sides of the block occupied by the house and offices.

6. We have endeavoured to ascertain the cost at which it would be possible to acquire Hertford House for the nation and to adapt it for the purposes of a public exhibition. There is reason to hope that the leasehold and the freehold interest may be obtained for between 60,000*l.* and 70,000*l.*, and the cost of the above alterations would, according to Mr. Taylor's estimate, amount to about 24,000*l.*, making a total cost of some 90,000*l.*

But Mr. Taylor's estimate was, it must be observed, only approximate; nor does it include electric or other lighting, a question which will have to be faced by the trustees. It was, moreover, made upon the assumption that the alterations would be carried out in such a manner as to make the new galleries harmonise with the existing galleries rather than with the reception-rooms, which are decorated with more elaboration and in a more costly style than would be requisite in the case of galleries intended for purposes of exhibition only. We are, however, strongly of opinion that, in any alterations or additions which may be found necessary, the general character of the existing decorations should be maintained.

7. We may here mention that the complete isolation of the Hertford House block, which is bounded on one side by Manchester Square and on the other three sides by George and Manchester Streets and Spanish Place, renders it specially safe from danger of fire from adjoining properties.

The National Gallery Proposal.

8. We have now to consider the proposal that the Wallace collection should be removed from Hertford House, and should be accommodated in the immediate proximity of the National Gallery. It is argued in support of this that the Wallace collection should be made as much a part of the National Gallery as the terms of the bequest permit, that the juxtaposition of these collections will be a gain to each, and that it will be convenient for persons interested in the fine arts to pass freely from one collection to the other. It is urged, and not without force, that these considerations are entitled to special weight owing to the fact that in the Wallace collection of

pictures certain schools, which are badly represented or almost unrepresented in the National Gallery, are represented by a number of extremely fine examples.

It must, on the other hand, be borne in mind that the terms of the bequest absolutely forbid anything which could properly be described as a mixture of the two collections. The precise amount of separation which is necessary in order to comply with the directions of the testatrix may be fair matter for discussion, but we hold strongly that it must be real and effectual.

9. It is, however, when we come to consider how the necessary space might be provided in the neighbourhood of the National Gallery that we are confronted by the most formidable difficulties. For many years past the attention of the trustees, and of successive Governments, has been directed to the necessity of providing for and anticipating the natural expansion of the National Gallery. During the last twenty years 246 pictures have been purchased by the nation, and 218 pictures have been presented or left to the Gallery. There is every reason to hope that this growth will be maintained, partly owing to the generosity of private donors, and partly by judicious acquisitions at the expense of the public.

In 1878 and in 1887 extensions to the rear of the eastern and central portions of the main building were carried out, and an understanding has been come to between the trustees on the one hand and the Treasury and the War Department on the other, that a further extension to the rear of the western wing is to be carried out before long. This extension is to occupy a part of the space now occupied by St. George's Barracks, a portion of the troops being with this object removed from those barracks to new barracks at Millbank.

The War Office has always insisted on the necessity of retaining behind the National Gallery an amount of barrack accommodation sufficient at least to provide for one company of infantry and the recruiting depôt, and also sufficient open space for parading troops. It is no part of our duty to express an opinion upon this point, but it is evident that, if this view is to prevail, there can be no room for any extension of the National Gallery upon adjoining land at present the property of the State, except that referred to above. This being so, we hold that it would be most inexpedient to appropriate for any other purpose an area which is specially relied on to meet the normal growth of the national collection of pictures.

It is true that the trustees have lately decided to remove about 100 pictures from the National Gallery to the new Gallery of British Art at Millbank, and the transfer of these will no doubt place a certain amount of additional space at the disposal of the director and the trustees. It must, on the other hand, be borne in mind that parts of the Gallery are already inconveniently crowded, and we call attention to the evidence of Sir Edward Poynter as to the state of the rooms containing the Spanish and earlier Flemish pictures, for both of which additional space is urgently required.

10. Even, however, if it were possible to appropriate, for the exhibition of the Wallace collection, the whole of the space now intended to be given for the extension of the National Gallery, that space would, in our opinion, not be adequate for the purpose. The evidence points to the conclusion that it would certainly not be sufficient unless the ground floor were brought into use. The ground floor of the National Gallery compares, however, unfavourably with that of Hertford House in regard to light, and it is not at present the practice of the National Gallery authorities to use it for purposes of exhibition.

A further objection to this site is to be found in the fact that it could be approached only by means of a somewhat undignified entrance from Trafalgar Square, passing through the basement of the National Gallery buildings or from an entrance to the rear of the Gallery and opening upon Orange Street, a thoroughfare very unsuitable for the purpose.

11. It is therefore, in our opinion, beyond question that were it decided to bring the Wallace collection and the National Gallery together it would be necessary to acquire a site for that purpose adjoining the latter. That to which our attention has been specially directed lies to the west of the Gallery buildings, and may be described as the block bounded on the south by Pall Mall East, on the west by Hedge Lane, on the north by a narrow street running towards St. Martin's Lane, and on the east by the National Gallery buildings and the barracks. The area of this site, which is mainly occupied by the business premises of Messrs. Hampton, is about 33,000 feet. In the opinion of Mr. Taylor it could not be acquired at a less cost than 300,000*l.* or 350,000*l.* To this amount would have to be added the cost of a suitable building, in a style of architecture appropriate to its position and to the importance of its contents. The cost of such a building is estimated by the same witness at about 125,000*l.* or more.

The intrinsic merits of this site are, we think, obvious, and its acquisition by the State would have the additional advantage of giving to the National Gallery increased security from the risk of fire. The cost no doubt would be very large, but we should not consider ourselves precluded from recommending

this solution of the problem merely on the grounds of its expense if it appeared to us that its superiority over every other was decided and incontestable.

12. It was suggested to us that an equally suitable site might be obtained to the south of Leicester Square upon a block bounded on the north by Spur Street, and lying south and west of Leicester Square. The cost of purchasing this block would, in the opinion of Mr. Taylor, be between 250,000*l.* and 300,000*l.*, whilst the cost of building upon it would, owing to its greater extent, slightly exceed his estimate of building upon the Hampton site. We are of opinion that the purchase of this site, while possessing no advantages over those of the Hampton site, would in other ways be much less desirable, and we have not pursued the question further.

13. In regard to both the above alternatives, the evidence of Mr. Taylor shows that it would take from five to six years to obtain possession of any site already occupied by business premises in the neighbourhood of Trafalgar Square, and to construct the necessary buildings upon it. The long delay which would thus arise would, in our opinion, be regrettable, especially as it is provided that the Wallace collections may not remain, as a temporary arrangement, for more than four years at Hertford House, during which period they could not, without great difficulty, be thrown open to the public.

An Independent Site.

14. The alternative of acquiring and erecting suitable buildings on an independent site in a central position is open to the same objections as to cost and time which appear so strong in the case of the National Gallery proposals; and, on the other hand, is without many of the advantages which are claimed for those proposals. We have, therefore, not considered it necessary to examine this alternative in detail.

Conclusion.

15. In view of the above considerations, we are of opinion that Her Majesty's Government would be well advised if they were to arrange that the collection recently bequeathed to the nation by Lady Wallace should be allowed to remain at Hertford House, the premises being suitably altered for the purpose; and we end by recapitulating briefly the reasons which lead us to that conclusion:—

(i.) Such an arrangement would be in accordance with the terms of the bequest, and would, in the view of the executors, give effect to the wishes of the testatrix.

(ii.) It would, more than any other arrangement, preserve the distinctive character of the collection, and would retain it within the building in which its owners had placed it, and which they had adapted for its reception.

(iii.) It would be much the less costly of the alternatives suggested.

(iv.) It would avoid the risks inseparable from the removal and rearrangement of the collection.

(v.) It would provide a museum which, owing to its complete detachment from other buildings, would be specially free from risk of fire.

(vi.) It would avoid delay and afford the public an opportunity of entering into the enjoyment of this priceless assemblage of works of art within a few months of the present time instead of five or six years hence.

Constitution of the Trust.

16. There remains the question of the constitution of the trust in which the collection should be vested. We understand that, under the terms of the will, a trust must be created, of which Mr. Murray Scott, the residuary legatee, must be a member.

In considering this question it must be borne in mind that although it is desirable to retain as far as possible the arrangement of the collection made by Sir Richard Wallace himself, yet, even if it be decided to retain the collection at Hertford House, there will be of necessity, for reasons given in the earlier part of this report, certain structural alterations to be effected, and as a consequence to some extent a redistribution of the contents of the galleries. It follows that the trustees will at first have before them a very laborious task. When once the collection shall have been housed and rearranged there will be little for them to do, for in this case there can be no expansion by purchase, no diminution by weeding out or removal.

In appointing the first trustees the Government will, in our judgment, do well if they select representatives of the trustees of two great national collections, viz. the National Gallery and the British Museum, say two from the former and one from the latter, together with other gentlemen of experience and leisure, some of whom might be willing to act as a sub-committee of their co-trustees in superintending the structural alterations in the first place, and in the second the redistribution, so far as may be necessary, of the collections.

We think that the trustees should not exceed seven in number, *i.e.* Mr. Murray Scott, two trustees of the National Gallery, one of the British Museum, and three others.

17. It will be necessary to appoint a paid curator, whose duty it will be to catalogue the collection, carry on such correspondence as may arise and have control of the staff under the trustees. The work of cataloguing is one which should be proceeded with at once, inasmuch as there appears to be no complete inventory of the collection in existence. This will be a long and difficult work, and in some cases—as, for instance, in that of the armour—special experts will have to be consulted. Upon the immediate importance of beginning the catalogue we cannot lay too great stress.

The following separate report is by Sir E. J. Poynter, P.R.A. :—

1. I am in full agreement with the main report in all its conclusions as to the adaptation of Hertford House, if it be decided to retain the Wallace collection on that site; but as I do not agree with the conclusion in paragraph 15, I have thought it better not to sign the report.

2. I also agree that the proposed extension of the National Gallery to the north of the western wing is required for the normal growth of the national collections.

3. But I think that the immense advantage to the public in having the two collections, each of which supplements the other in its weak points, in close proximity, is not sufficiently dwelt upon in the report. An opportunity is presented for making what would certainly be the most completely representative picture gallery in the world, affording unrivalled opportunities for study in every school of painting, and the whole forming a collection of unequalled magnificence which any nation would be proud to possess.

This opportunity would be afforded by constructing a museum, as suggested in paragraph 11 of the report, on the site to the west of the Trafalgar Square Galleries, at present occupied by Messrs. Hampton's and other premises. This scheme is, doubtless, far more costly than the proposed purchase and alteration of Hertford House; but it is quite certain that with the growing impatience of the public at the risk of injury by fire to the National Gallery, incurred by the immediate proximity of the furniture shops and warehouses, the expense of acquiring this site must sooner or later be incurred. The danger is a real one and cannot be shirked. The expense therefore of building a museum for the Wallace Collection on this site may be said to be that of providing the building, roughly estimated at 125,000*l.*, as against 90,000*l.*, the estimated cost of purchasing and altering Hertford House.

4. In any such proposal, however, the question as to what constitutes a separate site has to be considered. In providing that the Wallace collection shall not be mixed with any other, or have any part of another collection mixed with it, the intention of the testatrix appears to be the very natural one that due honour should remain attached to the founders of so exceptional a collection and to the munificence of the bequest. I do not understand such a provision to mean that it is never to be brought into relation with any other collection. In my opinion, if the scheme suggested above were adopted, and a museum were built adjoining the National Gallery with a separate entrance, the Wallace collection being kept as a separate entity within its four walls, internal communication might be established with the rooms of the National Gallery to the great advantage of both collections, and the Wallace bequest would be no less a separate collection because the public could pass between the two collections without having to go out into the street; such a separation would be "real and effectual" (paragraph 8 of the Report).

5. There is another point in connection with the Hertford House scheme on which I touched in my evidence. The arguments put forward in favour of this scheme are to the effect that by retaining the collections in Hertford House we should preserve for the public an example of a splendid private house, or rather palace, enriched with treasures of art, collected with judgment, and displayed and arranged with the great skill and taste of a distinguished connoisseur. But it is precisely this palatial display and this skilful arrangement which it is proposed to destroy. When reception-rooms richly furnished and hung with pictures are converted into top-lighted galleries; when the armouries arranged with so much care and with the assistance of a specialist are removed from the galleries built specially for them and placed in a totally different part of the building; when furniture, instead of appropriately decorating the rooms, is disposed so as to allow of the free circulation of the public, what becomes of Sir Richard Wallace's arrangement? When, in fact, the palace is converted into a museum, what becomes of the palatial residence?

6. Under these circumstances I am of opinion that, seeing that Hertford House, if purchased, must be converted into a museum providing for the free circulation of the public (a vital point in any scheme), it would be better for the collection and more to the public advantage that a special museum should be built on a site (which must some day be acquired) where it would be more centrally situated and with the immense advantage of ranging the collection in contact with the present national collection in Trafalgar Square.

As regards the question of delay, it will not be argued that, in view of an arrangement which, if adopted, would be adopted for all time, the impatience engendered by the delay of a few years could be taken into serious consideration; especially as means could no doubt be devised of admitting the public, under certain restrictions, to Hertford House while the new building was being carried on, in which case the house could really be seen for a time almost as Sir Richard Wallace left it.

THE INFLUENCE OF EXAMINATIONS ON TECHNICAL EDUCATION.*

SCHMES of examination influence the education of a nation mainly in three ways: in the first place, they serve to mark out lines of study by the syllabuses they set forth; in the second, they fix standards of attainment by the amount of knowledge they require for various grades of success; and lastly, they offer incentives to students and teachers in the shape of the distinctions and prizes which reward conspicuous success. The influence of any particular scheme of examination on the progress of education is good or bad, just in so far as its syllabuses are wisely chosen, its standards of success fixed neither too high nor too low, and its distinctions and prizes so awarded as to offer a premium for intelligent work rather than for mere "cramming" of facts and theories.

It is proposed in this paper to consider to what extent the principal examinations, for which students of commercial and technical subjects enter, have exercised a beneficial influence on the progress of education in England, and to suggest certain directions in which alterations may be desirable.

The examinations which will be reviewed are those of:—

- (1) The Department of Science and Art;
- (2) The City and Guilds of London Institute for the advancement of technical education;
- (3) The Society for the Encouragement of Arts, Manufactures, and Commerce;
- (4) The Universities of Oxford, Cambridge and London; and
- (5) The London Chamber of Commerce.

It will be seen that the list makes no pretence to be exhaustive, though it is believed to be thoroughly representative.

I.—Examinations of the Department of Science and Art.

No examinations have exerted a more widespread influence on the progress of technical education than those of the Department of Science and Art, and those who are best acquainted with the facts will be prepared to admit that, though the examinations in question may have done not a little harm, their influence has, on the whole, been beneficial, and that steady improvement has been made in the Department's syllabuses and modes of action.

In the earlier periods of the Department's existence it was driven to adopt bad methods, first, by the lack of competent teachers; secondly, by the almost entire absence of facilities for practical work in connection with the subjects of scientific instruction which it endeavoured to foster; and lastly, by the fact that the clerical division of the Department's staff far exceeded both in numbers and apparently in influence that portion of its officers which had some knowledge of science, art and technology, and understood the difficulties of the teachers and the requirements of the students. All this has been and still is steadily changing; the number of competent teachers is rapidly increasing; well-equipped laboratories of all kinds are springing up all over the country, and the expert side of the Department's staff has been greatly strengthened. The appointment as Director for Science of a former inspector and distinguished scientist, Captain Abney, has already led to great improvements, and creates a hope that still better things may be in store.

Within the last few years the Department has taken steps to recognise practical work, not only in chemistry and metallurgy, but also in physics and biology. It is to be hoped that in a short time it will not merely recognise but will require this, and that it will take steps to encourage practical work in connection with other subjects such as mechanics and the theory of the steam-engine.

The recent establishment of separate day and evening examinations encourages the belief that the Department may, in time, see its way to draw up separate syllabuses suitable respectively for the pupils in the day schools connected with it and for the adult artisan pupils of its evening classes.

* A paper by Professor J. Wertheimer, principal of the Merchant Venturers' Technical College, Bristol, and hon. secretary of the Association of Technical Institutions, read at the International Congress on Technical Education at the Society of Arts.

II.—Examinations of the City and Guilds of London Institute.

While the Department of Science and Art owes its origin and the funds it distributes to the action of Parliament, the City and Guilds of London Institute is maintained by the ancient trades' corporations of the Metropolis.

The examinations of the Institute have undoubtedly exercised a beneficial influence on the teaching of technology; but there is still room for improvement in the syllabuses of the examinations, and it is very desirable that the Institute should insist more largely on evidence of practical skill.

The professional element on the examination board is at present entirely drawn from the staffs of the two colleges which the Institute controls, and while every one must be pleased to see these eminent teachers on the Board, it is greatly to be desired that the Institute should associate with the professors in its own colleges representatives of the professors and teachers in the leading provincial technical schools and colleges.

At present the examinations of the Institute in many subjects are quite beyond the reach of the majority of young artisans. This is unfortunate, and a great impetus to apprentices to study would be given by the subdivision of the work required for the ordinary grades into two or even more parts, which might be taken in different years. It would also tend to popularise the examinations and the classes preparing for them if, in place of the present certificates, a "journeyman's" and a "foreman's" certificate respectively were issued to artisans who produced evidence of the necessary training in the workshops of an approved firm, and who subsequently passed the Institute's theoretical and practical examinations. The honours grade certificate might then be made still more difficult of attainment than at present, and would be suitable for those desirous of becoming captains of industry. It is only necessary to point to the fact that in mechanical engineering only 481, in boot and shoe manufacture only 208, and in calico printing only 31 candidates sat for examination in 1896, in order to convince all concerned that the Institute still covers only a small part of the field which is open to it.

III.—Examinations of the Society of Arts.

The Society of Arts (to give it the title by which it is best known) does for commerce what the City and Guilds of London Institute does for technology. Meeting, as this Congress does, in the rooms of the Society, it is but proper that it should note specially the deep obligations of the business world for the care with which the Society has fostered training in commercial subjects. Its examinations are steadily increasing in favour, and its certificates are with justice highly valued. Probably for financial reasons there is, however, in the examinations in modern languages no provision made for testing and giving credit for a candidate's ability to speak these; it is to be hoped that a way may be found to remedy this defect, and thus indirectly to help British merchants who may wish to find commercial travellers able to meet, on approximately equal terms, those whom our German cousins send out so well prepared and in such abundance. It would also be an improvement if the Society were to issue both "Junior Clerks'" and "Senior Clerks'" certificates to students who gave evidence of satisfactory service for, say, three and six years respectively in houses of business approved by the Local Chamber of Commerce, and who subsequently passed certain of the Society's examinations; certificates of this kind would soon come to possess a very high value in the commercial world.

IV.—Examinations of the Universities of Oxford, Cambridge and London.

These universities influence technical and commercial education in two ways. They grant degrees to those about to become teachers, and by the local examinations of the ancient universities, together with the matriculation examination of the University of London, provide tests of the completion of the substratum of general education which students should possess before they enter upon a course of higher technical or commercial training. As regards Oxford and Cambridge, enormous strides have been made of late years in the provision of laboratories and apparatus, and their distinguished students of electricity, for example, are no longer indebted to text-books alone for their knowledge of dynamos.

Oxford and Cambridge, unfortunately, do little to encourage undergraduates to obtain a conversational knowledge of modern languages. Of course a university student should require a thorough literary knowledge of a modern language, but it is difficult to understand why, e.g. in the Modern Languages Tripos at Cambridge, no marks are assigned for ability to speak the languages chosen, though candidates who can do this have their names distinguished by an asterisk.

The University of London has greatly helped technical education by requiring for its degrees in science an adequate amount of practical work, in addition to severe theoretical examinations. As a result, many of the most important teach-

ing posts in technical schools and colleges are filled by graduates of this university.

The local examinations of the universities of Oxford and Cambridge have lately been greatly improved by the introduction of a new, though unfortunately optional syllabus for elementary science, which involves something more than the mere book-knowledge still sufficient for success under the alternative schemes. It is to be hoped that practical work in science may soon be included in the matriculation examinations of the University of London.

V.—Examinations of the London Chamber of Commerce.

The London Chamber of Commerce has put forth certain schemes for commercial education and has held examinations thereon, but so far these examinations have not been very generally accepted. A very important point in the syllabus of the Chamber is that in modern languages conversational knowledge is required. The multiplication of examining bodies is, however, in every way undesirable, and it is difficult to see why arrangements could not be made by this Chamber—or better still by the Association of Chambers of Commerce of the United Kingdom—and the Society of Arts for an amalgamation of their forces in order to secure one set of examinations for commercial certificates for the whole country.

General Observations.

It behoves us to watch closely any attempt to establish new examinations. The technical instruction committees of some county councils are already instituting examinations of their own; in a very few cases these may be necessary to meet special local requirements. But as a rule they are not needed, and it would be wiser to endeavour to modify existing examinations, if necessary, rather than to establish new ones.

In fact there are not a few of us who would be prepared to make the establishment of a new examination a misdemeanour at the least, unless the examination took the place of one or more already in existence.

As another instance of unnecessary examinations, that conducted by the Worshipful Company of Plumbers may be mentioned. The examinations of the City and Guilds of London Institute in plumber's work are at the least as well arranged, and it is to be hoped that the Company may soon see its way to accept the Institute's examinations and withdraw its own.

In the important subject of cookery we suffer at present from the too great energy of the rival examining bodies. It would be matter for congratulation if they would consent to hand over their examining functions to some external body such as the City and Guilds of London Institute; the certificates issued would then have the same value all over the country, and their validity would not be confined to certain comparatively limited areas as at present.

In conclusion, it is, however, gratifying to note that in the departments of technology and commerce we do not find that multiplication of examinations which is so great a misfortune in the region of general secondary education.

THE PANTHEON, PARIS.

THE church of St. Geneviève, which is once more the Panthéon, was built by Soufflot for Louis XV., who allotted to the erection an additional four sous on every ticket in the lotteries. The annual produce of this was valued at 364,000 livres, nor does it appear that the amount fell short, but in the beginning the directors anticipated their revenues in the purchase of the ground, and perhaps also in the conduct of the edifice; and various other expenses and some considerable buildings were saddled on the funds, so that in 1780, after the death of Soufflot, and twenty-five years after the commencement of the building, the works were at a stand for want of money. In 1784 a precise estimate was formed of the sums yet required, and it was found that, to complete the building according to Soufflot's plan, it would require 5,340,000 livres, and 1,203,000 for the square round it and for the avenues; while the amount of the funds appropriated, after paying the interest of the sums borrowed, was 193,500 livres per annum, so that it would have required thirty-four years to terminate the work, and ten years and a half more to repay the debts. M. Rondelet, in his "Mémoire Historique," enters into an explanation of the proposed mode of raising money for the purpose of carrying on the works. But the income seems to jump from 193,000 to 278,000 without any cause; they were to borrow 400,000 livres per year, and to repay 100,000 of the old debt, which seems just the same as borrowing 300,000. For the loan they were to pay interest at five per cent., and by this method it was calculated that they should raise enough to complete the building and surrounding improvements in twelve years. In fourteen years afterwards, supposing the funds to remain untouched and no further expenses to intervene, the creditors might be paid, but if by any accident the works should be prolonged a

few years more than was contemplated in this estimate, the interest of money borrowed would exceed the funds. For five years, *i.e.* 1785-89, the works seem to have gone on with spirit, and near 2,500,000 livres were expended. At this time all the solid work of the edifice was completed, and it appears that about the end of 1789 the first serious alarm was excited, although some cracks had been observed as early as 1776. In 1789 a stone broke in one of the pillars of the dome, and in replacing it the faulty construction was betrayed.

It is doubtless very interesting to an architect to understand the construction of those buildings where any difficulty was to be overcome in which the efforts of the artist have perfectly succeeded. It is, perhaps, still more instructive to trace the causes of failure in those which have exhibited some considerable defect. The true maxim of an architect is to spare nothing necessary to make the building perfectly firm and durable, but at the same time to admit nothing superfluous; a building which stands secure might perhaps have been equally secure with a portion of materials, and consequently of expense, considerably smaller; a building which fails we are sure was not strong enough, and if it do not begin to fail till after it has received its full weight it becomes particularly worthy of attention as an elucidation of the minimum which may be employed, or rather, which must be avoided, for the evil on one side is so incomparably greater than that on the other that it would be a folly not to err systematically in some degree by giving more strength than is absolutely necessary. The piers of the dome of St. Geneviève did not so decidedly yield to the pressure as to stop the progress of the building till nearly two years after the dome was completed and the centres removed. It was not till 1795, when, in order to adapt the edifice to its republican destination, some masses of hard stone intended to receive the ornaments were cut away, that any considerable defects became sensible. The slight motion given by the repeated jarring of this operation was sufficient to destroy the equilibrium of the forces.

The soil on which this church was built had been found on an examination previous to laying the foundations to be full of pits, some as much as 80 feet in depth, which had been dug to procure an earth for a sort of coarse pottery, a circumstance which does not give us a favourable idea of any part of the foundation. These pits were very carefully filled up, and the foundations and erection of the vaults carried on so as to give a perfectly firm basis for the superstructure. This operation has completely succeeded, and does not exhibit the slightest trace of failure or settlement. These works were begun in 1755; in 1764 Louis XV. placed the first stone of one of the pillars of the dome, an honour which is supposed to have excited some jealousy against the architect. Great clamour was raised against the price paid for cutting the stones, and the cautious and scientific method of proceeding at first adopted was abandoned exactly at the point when care and nicety were most necessary. The piers, consequently, instead of being built of stones perfectly squared with true beds, were composed of such as presented merely an even face, whilst frequently the internal mass was very defective.

Soufflot himself seems to have directed the beds of the stones to have been wrought smooth for a depth of 4 or 5 inches from the external face, and the remainder to have been roughly sunk three or four lines in order to receive the mortar; a method bad in itself, as it evidently throws the principal weight to the face of the pier, *i.e.* to the weakest part, instead of spreading it equally over the whole surface, or with rather a tendency to the centre. Even these directions had not been attended to; but the builder, content to make the outside of his work fair, had used stones in many instances which were wedge-shaped; and joints which only presented a thickness of one or two lines externally were 2 inches or 2½ inches wide on the inside; the filling-in stones by no means fitted their places, and the interstices thus left were so little filled with mortar that in one place, on examination, the work admitted several pailfuls of grout. In order to obviate any immediate ill effect from the unequal beds of the stone, *calles*, or little bits, generally, as it appears, of wood, were inserted in order to support each block to its level. Above the piers of the dome the work was better executed, both in principle and practice, and the internal surfaces were merely picked to hold the mortar, without any sinking, under the direction of Rondelet; yet even in this part the want of large stones has made it necessary to introduce a prodigious quantity of iron-work to support arches where the construction required a single stone.

The first appearance of weakness, as already observed, was in 1776, when on removing the centres of the great arches some few pieces flanced off, but they were of little consequence. In 1779, while they were continuing the drum of the dome, new appearances of the same sort occurred, and Soufflot employed workmen to "sawker" the joints in order that the weight might bear more upon the solid mass of the pier; and during this operation the *calles* were taken out wherever they came within reach. At the death of Soufflot, which happened

in 1780, an examination of the cracks and flanchings was undertaken, but it was not till 1788 that they began to replace the broken stones. Nevertheless, in 1797, when Rondelet first published his work, there were in one of these pillars 367 cracks, of which 138 formed *lezards*; 283 flanchings; 64 points where the stone had been crushed by the incumbent weight; 54 separations of the upright joints; 344 pieces renewed, 37 of which had been renewed a second time.

It is marvellous that under such circumstances they should have continued the work, since it was evident from the pieces twice supplied that the progress of the settlement was going on sufficiently to make itself sensible, even while the centering of the dome remained; yet it does not appear that any immediate mischief followed the striking of those centres, and it was not till 1796 that the ultimate stability of the edifice was considered doubtful. At that time a commission of architects was appointed to examine the state of the building, and report on the best means of proceeding. These gentlemen examined the piers and completely ascertained the defective mode of workmanship; and they found that the piers and columns under the dome had settled irregularly in consequence of it. One pier had sunk 5 inches and two lines, French measure, the whole of which must have taken place in the height of the columns (37 feet 8 inches), as everything above and below was firm. Such defects in the workmanship seemed sufficient to account for the failure of the construction; but it was necessary to know whether, if perfect, the piers would have had sufficient solidity, and whether there was any defect necessary to be attended to in the disposition of the weight above. Soufflot made some experiments to ascertain the pressure which the stone "du fond de Bagneux" used in these pillars would support; but it appeared probable that the instrument he used was defective. Rondelet therefore repeated the experiments, both with Soufflot's machine and with one of his own contrivance. According to the first, each pier would support a weight of 70,362,720 lbs., supposing it to be a single block of stone; according to the last, of 27,329,222; a tremendous difference, and yet the estimate is still probably too high, as even in Rondelet's machine some power is lost by friction. As however it is probable that from the bad construction of the piers the weight was not supported by more than a fourth part of the superficies, their strength, calculated on Rondelet's machine, would not exceed 6,832,305 lbs., while the weight of a quarter of the dome was ascertained to be 7,449,980. We must, however, be careful how we make use of these combinations of experiment and calculation, since it would appear from them that the piers of the bridge of Neuilly to support arches of 120 feet span, instead of 13 feet thick as they actually are, need only have been about 4 inches, and the walls of a house five storeys high require only three lines and a half in thickness at the bottom. As for the distribution of weight the commissioners condemned the method adopted, owing to a change in the plan during the progress of the work, of making the drum of the dome pass a little on the *outside* of the line of the uprights; but they contented themselves with recommending the establishment of centering to relieve the weight, while the broken stones were removed and replaced with such an incrustation carefully worked as would be sufficient to sustain the whole building.

All the principal architects before Soufflot have given their domes a strong tendency towards the centre, but it does not appear that this is necessary, nor even in most cases expedient; nor was that of St. Geneviève faulty from the adoption of a different maxim any further than as it tended to throw a larger portion of the weight on the three-quarter columns at the acute angles of the piers.

The centres for this method of restoration were already ordered when, at the solicitation of the builder, another examination by the inspectors of the Ponts et Chaussées was ordered by the minister. In France the architects and engineers never agree; and, therefore, in order to have an opinion of their own, these inspectors, although they could not help finding the same causes of failure, yet voted the centering proposed by the architects unnecessary; stating that the defective construction of the piers, and the consequent danger of the building had been much exaggerated, and that the incrustation recommended was insufficient and injurious to the beauty of the architecture; and instead of this they advised the insertion of angular flying buttresses. This would have added to the load without increasing the strength of the edifice, since the direct pressure and not any lateral thrust was the source of the evil.

The architects and engineers continued debating while the evil was increasing. Two mathematicians were appointed to examine the reasons on both sides, but they declined pronouncing which was right, and it was agreed that the architects, the inspectors and mathematicians should each report separately to the minister of the interior. Other commissioners were appointed in 1798 who were frightened at the progress of settlement which had taken place in the two years preceding, and requested the immediate erection of the centres proposed by the architects; but unfortunately they desired that Rondelet,

Gauthier, inspector general of Ponts et Chaussées, and Patté, who had published in an early stage of the work some observations on the insufficiency of the piers, should be joined with them. The indulgence of this request produced new difficulties and new debates. At last in 1799 a commission of the members of the Institute recommended the completion of the erection of the centres, and this appears to have been executed; but nothing further was done till 1806, when it was decided to restore the building to its original destination as a church. The pillars were rebuilt under the direction of Rondelet on the principle at first recommended by the architects. The whole now seems perfectly firm, and the appearance of the building not at all injured.

It is certainly a beautiful edifice; the general proportions are good and there is much grace and elegance in the outline, but there are also many defects. The columns of the portico are too wide apart, there ought to have been eight instead of six in the front row. The two columns forming a projection on each side beyond the line of the portico are great blemishes, very injurious to the general effect, and the more so because they are palpably placed there for no other purpose than to enhance it, and the four internal columns on each side are most awkwardly doubled against the external columns and the pilasters. If instead of these eighteen columns there were sixteen, disposed like those of the Pantheon at Rome, this part would have been incomparably finer. The body of the building is too plain for the portico; the eye requires either pilasters or something which might produce a similar effect, to be continued all round, in order to preserve the same character throughout the edifice, or at least some returns at the north and south entrances of the magnificence of the western front. It is as necessary in architecture as in painting to avoid everything which makes an unconnected spot in the composition. The breaks which exist as apologies for the want of pilasters have a foolish and unmeaning effect; and the uninterrupted continuance of an ornament of the height of the capital is heavy and displeasing. Above this the pedestal of the dome by its plainness and simplicity forms a relief to the more ornamented portions of the building, and affords a noble base for the upper part. The columns of the drum are well proportioned and well arranged. The attic above them is perhaps rather too high, and the flat ribs of the dome itself are objectionable, especially when distinguished as they were by being painted yellow on a gray ground. This dome is triple, and the outer is in parts of its surface only 8 inches thick. It is not a portion of a sphere, but like that of most modern churches would form a point if the summit were not cut off to receive the lantern. This is right where a dome is elevated and surmounted by another form of edifice. In a building where a dome and its direct support constitute the whole of the apparent mass, or even where the dome forms the centre of a building not very high in proportion to its extent, the portion of a sphere is better; but where the effect of height is intended the somewhat pointed form of the dome maintains the general tendency to a pyramidal form. In its light and elegant appearance the interior resembles the church of St. Stephen, Walbrook, more than any other edifice in England; and like that perhaps is rather deficient in the solemnity which ought to accompany a religious edifice. There is no heaviness in any part, but in some respects rather the contrary appearance of insufficiency. The new piers are no stronger than seems necessary to support the work above; yet the disposition of the columns forming the nave into squares, each of which is covered with a shallow dome, though giving an air of lightness produces a certain degree of confusion, and is vastly inferior in majesty and sublimity to a nave with a continued vault leading to one central dome. It is perhaps this circumstance more than any other which communicates an air of gaiety, one might also say of levity, to the interior. The four square pillars over the columns which advance at the angles to support the smaller domes are preposterously little. There are other defects in the details of the building, but in spite of them all one cannot refuse it the rank of one of the most beautiful edifices in Europe.

GOVERNMENT COMPETITIONS IN AMERICA.

THE following regulations for competitions for Government buildings have been prepared for the enforcement of the Tarnsey Bill by Mr. Kemper, acting supervising architect, under the direction of Secretary Gage:—

By virtue of the authority contained in the Act of Congress, approved February 20, 1893, entitled "An Act authorising the Secretary of the Treasury to obtain plans and specifications for public buildings to be erected under the supervision of the Treasury Department, and providing for local supervision of the construction of the same," the Secretary of the Treasury hereby declares his purpose to enforce said Act with reference to such buildings as may be hereafter selected by him, subject to the following regulations:—

1. At least five architects of good professional standing, who are citizens of the United States, shall be invited by the Secretary of the Treasury to submit plans, drawings and specifications in accordance with the conditions set forth in these regulations; and such plans, drawings and specifications shall be passed upon as to merit by the commission herein provided for.

2. A commission shall be appointed by the Secretary of the Treasury, consisting of the supervising architect of the Treasury Department and two architects or experts in the construction of buildings, whose duty it shall be to judge and report to him as to the relative merit of the designs and plans submitted.

3. The office of the supervising architect will furnish full data and information as to cost and the general requirements of the buildings placed in competition under these regulations, and the successful architect will be awarded a commission to prepare complete plans, drawings and specifications and to locally supervise the buildings won in any competition.

4. The architect to whom said commission is awarded will receive in compensation for his full professional services, including local supervision of said building, a fee computed at the rate of 5 per cent. upon all sums up to 500,000 dols., $3\frac{1}{2}$ per cent. upon the next 500,000 dols. or any part thereof, and $2\frac{1}{2}$ per cent. upon any excess beyond 1,000,000 dols.

5. It must be understood that no claim shall be made upon the United States by any successful competitor for any fee, percentage or payment whatever, or any expense incident to, or growing out of, his participation in this competition.

6. The Department agrees to make selection from the designs submitted if in its opinion one suitable in all respects as to design, detail and cost be submitted, but expressly reserves the right to reject any and all plans, designs and specifications submitted, and to reopen the competition if, in the opinion of the commission herein referred to, or of the Secretary of the Treasury, no design suitable in all respects has been submitted.

7. Each competitor must submit with his plans a detailed estimate of cost.

8. It must be understood that a competitor will forfeit all privileges under these regulations who shall violate any of the conditions governing this competition, or who shall seek in any way, directly or indirectly, to gain advantage by influencing in his favour any of the commission.

9. No member of the commission herein referred to shall have any interest whatever, direct or indirect, in any design submitted in this competition, or any association with or employment by any of the competitors, and no employé of the Treasury Department shall be allowed to enter the competition herein provided for.

10. Each set of drawings, with its accompanying description, must be securely wrapped and sealed and addressed to the "Secretary of the Treasury, Washington, D.C.," plainly and conspicuously marked with the name of the building under competition, and without any distinguishing mark or device which might disclose the identity of the competitor.

11. There must be enclosed with each set of drawings, &c., a plain white opaque envelope, within which the competitor will place a card bearing his name and address. The envelope must be securely sealed with a plain wax seal, having no impression, legend, device or mark upon it which might disclose the identity of the competitor.

12. Upon opening the packages containing the drawings the commission will number the envelope containing the name and address of the competitor, and will place the same number upon each drawing, plan, specification, &c., submitted by him, and will preserve unopened the envelope containing such name and address until final selection shall be made.

13. The commission shall place out of competition any set of drawings as to which the conditions of these regulations have not been observed, and examine those remaining, giving to each the rank to which, in their judgment, its merits entitle it, and submit their findings to the Secretary of the Treasury.

14. The selection of one of the designs by the Secretary of the Treasury, and its subsequent approval by him, the Postmaster-General and the Secretary of Interior shall be final and conclusive.

15. In the event that the architect to whom the commission is awarded should prove to be an incompetent or improper person, the Secretary of the Treasury expressly reserves the right to remove him, to revoke the commission awarded him and to annul the contract entered into with him; but such architect shall receive equitable compensation for the work properly performed by him up to the time of his removal, to be fixed by the Secretary of the Treasury.

16. The architect to whom the commission is awarded shall revise his competitive drawings to meet the further requirements of the Secretary of the Treasury, and upon the basis of these revised preliminary drawings shall prepare full detailed working drawings and specifications for said building, and shall thereafter from time to time make such changes in the plans, drawings and specifications as may be directed by the Secretary of

the Treasury, for which just compensation shall be allowed, but no changes in the plans, drawings and specifications shall be made without written authority from the Secretary of the Treasury.

17. The architect to whom the contract is awarded shall, at his own cost and expense, when required to do so by the Secretary of the Treasury, make such revision and alteration in the working drawings and specifications of said building as may be necessary to insure its proper construction and completion within the limit of cost as furnished by the office of the supervising architect.

18. The sum upon which the architect's commission is to be computed shall be the sum of money expended for the actual construction cost of the building, as ascertained by contracts awarded, not including furniture, gas and electric light fixtures and electric light plants.

19. The compensation herein stipulated to be paid to said architect shall be in full payment of all charges for his full services, inclusive of all travelling and other expenses.

20. The architect's commission shall be paid as the work progresses in the following order:—

One-fifth of fee when preliminary drawings are completed and approved in the manner herein provided; three-tenths of fee when general working drawings and specifications are completed and copies delivered to the supervising architect, and balance of percentage monthly, upon the basis of vouchers issued in payments for work performed.

21. Until the actual cost of the building can be determined the fee of the architect will be based upon the proposed cost of the work, as above indicated, and will be paid as instalments of the entire fee, which will be finally based upon the actual construction cost of the building when completed.

22. The Department will provide a competent superintendent of construction, whose qualifications shall be passed upon by the architect, but the selection must be made from a list of not exceeding six names proposed by the Secretary of the Treasury.

23. The architect is to provide for the use of the Treasury Department one set of tracings of all working drawings and of revised competitive drawings, two copies of specifications and one copy of detailed estimate of cost of entire building, all of which will remain in the custody of the Department, and to be and remain the property of the United States and not of the architect, but such drawings and specifications shall not be used for any other building. And the office of the supervising architect will furnish for the use of intending bidders all necessary photographic duplications of plans and copies of the specifications.

24. Upon the award of the contract to the architect all designs of unsuccessful competitors will be returned to them, and no use will be made of any of the drawings not accepted, or of any part that may be original, without consent of the author thereof.

25. Payments upon the work of construction under contract will be made monthly, at the rate of 90 per cent. of the value of the work actually executed and in place, upon vouchers certified by the architect in charge and countersigned by the superintendent of construction representing the United States Government, which will be paid by a disbursing officer appointed by the Secretary of the Treasury.

26. The supervising architect of the Treasury Department will receive the proposals for contracts to be awarded, and shall likewise determine the manner in which the various branches of the work are to be contracted for.

27. All contracts, except for exigency expenditure, shall be properly advertised for thirty days, and shall be awarded by the supervising architect, with the approval of the Secretary of the Treasury, to the lowest responsible bidder.

28. All further details necessary properly to carry out these regulations may be arranged by the supervising architect from time to time, provided they do not conflict herewith.

29. The foregoing regulations shall be subject to modification and change at the pleasure of the Secretary of the Treasury.

ROYAL ARCHÆOLOGICAL INSTITUTE.

THE annual summer meeting of the Royal Archæological Institute was opened at Dorchester on Tuesday last, and will continue during the week. There was a large attendance of members, who were officially welcomed at the town hall by the Mayor and local committee, consisting of prominent members of the Dorset Antiquarian Society. The secretary of the meeting is Mr. Mill Stephenson, and the local secretary is Mr. H. J. Moule, curator of the Dorset County Museum. The president for the year, General Pitt Rivers, delivered his presidential address, dealing chiefly with his excavations at Rushmore and his discovery of flints in Egypt. Among those present were Sir H. Howorth, Professor Boyd Dawkins, Professor Clarke, the Rev. Sir T. Baker and other well-known

archæologists. After the reception the members visited various objects of interest in the town, under the guidance of Mr. Moule, including the Royal Amphitheatre and the County Museum. In the evening the antiquarian section was opened by Professor Boyd Dawkins. The arrangements for the week include visits to Sherborne, Wareham and Corfe Castle.

TESSERÆ.

Wolsey and Architecture.

WOLSEY'S taste and knowledge of architecture must have been great. Who can see the tower of Magdalen College and doubt it? And Christ Church and Hampton Court, though mutilated, bear sufficient testimony to his knowledge and love of that excellent art of architecture which none but superior minds should venture to meddle with, for if it makes greatness and wisdom conspicuous to the world, it makes folly so too, and therefore the more contemptible. Architecture is the natural constructive instinct of a great mind, the throwing off into palpable form of high thoughts. It is a part of that noble constructiveness which would build up institutions, the practical language of a governing mind. It is an empire in itself, in which genius loves to reign and be supreme. It was highly characteristic of Wolsey. We believe all really great men love architecture. A man who builds to himself a notable palace or house, and by his arrangements adequately shows forth and appropriates a fine estate, makes to himself at least a centre of the world, to which all things come or seem to come, and from which all thoughts radiate by enclosing apparently so much of the world's wilderness as he wants; all within his eye's reach is his real, and all without his imaginary domain. He creates the happiest delusion of space, regulates it by his own ideas, making it what he would have it and ornaments it to charm him. In a fair and noble mansion a man must, in some degree, feel himself a king, for his will has sway and room to move in. It has a tendency to elevate, to give him character, decision and that dignity which ever arises from repose within one's self; that need not be shoved and hustled from meditation and reflection by the too near proximity of ill-assorted things and persons. We look upon the taste for architecture as a national good. It is the means of raising families to a visible responsibility, giving them something to keep up and to hand down to others, greater than the littleness of uncultivated, unadorned republican man. The other arts require it, and all arts thus assisting each other, build up and constitute all that is beautiful in the world, visible and moral. How hard is it to give up anything we make and call our own. Now in nothing was Wolsey's superior greatness more shown than in the readiness of so large a sacrifice as Hampton Court. Had he pride, he had enthroned it here, but his pride was a part of him. Driven out forcibly from one palace, it had a sure refuge in himself. Nothing, no outward act of malice or tyranny, could rob the world's history of Wolsey. He knew it, and even in his fall was greatest. This noble fabric of Hampton Court was, however, readily resigned by Wolsey into the king's hands, who subsequently seized, too, his palace afterwards called Whitehall. It is a curious fact, and one that marks a visible retribution upon things, names and persons, whereby a sort of moral history of the world is written by a divine hand and carried on in continuance by striking incidents; it is a curious fact that these two palaces of Wolsey, as they are monuments of the rapine of royalty, so are they of the humiliation of royalty.

Da Vinci and Correggio.

The distinction betwixt the elements of art and science being kept in view, the strongest point of contrast between Leonardo da Vinci and Correggio is arrived at. In other respects they at once stand connected and opposed, but in this they belong to altogether different modes. In the instance of Leonardo it involves the essential character of his works. In respect to Correggio it is merely adventitious to that. Leonardo was mentally a seeker after truth—a scientist; Correggio was an assertor of truth—an artist. The whole endeavour and practice of Leonardo was experimental. His works are separate efforts, in many respects the one totally different from the other. Their sentiment is at times directed intellectually; on other occasions they appear to be regulated by moral impulse; and again, the expression of physical and material quality seems to constitute their intention. But in no instance can either be said to be thoroughly effected. In the method or material of their production there is consequently a corresponding variety. If there is any binding sentiment which may be considered to predominate in his pictures, it consists in a demoniac keenness in the expression of the heads, which leads away from and absorbs every other portion of them. If there is any prevalent method which may be considered at once to belong to such very differently produced works as the *Medusa* and the *Christ among the Doctors*, it

consists in a quality which was very general to the painters of the time, almost universal—their elaborately touched surface. His restless exertion attempted both the highest and lowest in art. It occupied itself with absurd and hideous caricature, and led him, after years of labour, to pronounce his picture of the *Last Supper* unfinished. He was an experimentalist, the necessary precursor to the unfolding of the discursive range of sentiment, the manifestation of which immediately followed. He is a dependent and aiding portion in the enunciation of Italian painting, and hence of that of modern Europe. Instead, therefore, of regretting the diversity of his pursuits—instead of lamenting their want of concentration—it should be seen that that which he aimed at was not compassed by any other individually; that the powers of the greatest names consisted in the enucleation of separate parts of that which his ambitious intellect yearned towards the production of as a whole; and that it was not until these separate manifestations had been made that another rose in Antonio da Correggio to take advantage of what had been done, and to attempt its union, but only to show that this was incompatible with the entirety of its different components, and that another limit—a distinct range of significance—was necessarily entered upon, less great and less worthy than those of Michel Angelo and Raphael, but although less extended and engrossing, more elevated than that of Titian.

Thirteenth-Century Windows.

There is no feature which is more attractive than a well-designed early Pointed window. The refinement of the curves of the outlines and openings is well supported by the delicate skill with which the mouldings are divided and subordinated, some following the great enclosing arch, some the leading lines of the tracery, and others confined to the sub-cusping or foliation which fills in the spaces enclosed. Where this distinction between the mouldings fitted for serious work and those intended for enrichment only is not observed, there you may always assume pretty safely that the work, whether old or new, is not from the hand of a master of his art. One class of window, the rose or marigold, may be said to have been brought quite to perfection in the thirteenth century, not only in England, but on the Continent also, and examples of it are very numerous; the decided circular outline seems to have lent itself much more naturally to a filling in with geometrical forms than to any of the special features which marked the subdivisions of the tracery in the later styles of window tracery.

Wells in Roman Churches.

Many are the sacred wells in Roman churches whose waters the devout are eager to drink on particular festivals, and we may trace this feeling to its origin in the high idea of the baptismal rite predisposing to ascribe mysterious efficacy to the pure element. Both the reputed prisons of St. Peter and St. Paul contain such wells; another, at S. Maria in Via, derives its sacredness from a Madonna picture found floating on it in the year 1253. In the Benedictine church of St. Callisto we see, through a door beside an altar, a well of great depth and width, quite unlike those of modern formation, in which Pope Calixtus I. suffered martyrdom, being thrown from a window of the house where he had been confined and had converted a soldier, his keeper. In the adjacent church, S. Maria in Trastevere, is kept the stone said to have been fastened to the neck of St. Calixtus when he was drowned. Many large black stones of the species called *pietra del paragone*, rounded but flattened at two sides, are to be seen in Roman churches, preserved as records of martyrs; and such they may be deemed, for weights of stone used to be hung to the neck, the hands or feet when scourging was to be inflicted. It is supposed that for this purpose were employed either weights originally serving for trade, or those sometimes marked with numbers to indicate what the law allowed for securing the persons of debtors. Such objects when for trading purposes used to be dedicated to Hercules as the God of Traffic.

Gothic and Renaissance Construction.

Who can stand among the airy arches of Amiens, Cologne, Chartres, Beauvais or Westminster and not be filled with admiration at the mechanical skill and beautiful combination of form which are united in their construction? But, say the modern critics, they are only proofs and a bungling contrivance. Let us examine this. Are the revived pagan buildings constructed with such superior skill as to dispense with these supports? By no means; the clumsy vaults of St. Paul's, mere coffered semi-arches, without ribs or intersections, have their flying buttresses; but as this style of architecture does not admit of the great principle of decorating utility, these buttresses, instead of being made ornamental, are concealed by an enormous screen going entirely round the building. So that, in fact, one-half of the edifice is built to conceal the other. One of the greatest defects of St. Paul's is its fictitious dome. The dome that is seen is not the dome of the church, but a mere construction for effect. The upper part of St. Paul's is mere imposing show, constructed at a vast expense without any legitimate reason.

The Nude in Greek Art.

SIR,—On perusing the short article which appears in your issue of July 23 anent the above subject, I was struck with the unsoundness of your argument in support of the representation of nude figures.

To be brief. You say, "The sculptor should and will show us men;" but is it a *sine quâ non* to the practise of his art that he should show them to us in an absolutely nude state? I take it he does not do so from an anatomical or medical point of view, nor because there is anything particularly beautiful about it.

You also say, "He knows of no princess, no king and no king's son, he busies himself only with men." This is right so far as personality is concerned, but it does not do to apply this reasoning from a moral standpoint.

You further say, "The laws of propriety or need are not the laws of art." That is so, but should not, in the interests of morality, of refinement, of education, the laws of art be made subservient to the laws of propriety or need? or do the latter laws, in value, take a secondary place? I have always esteemed morality as the foundation of civilisation; undermine this and we might as well be savages.

"All in man that is not humanity is contingent." True, but is not our whole system of civilisation made up of a mass of contingencies? I take it that all those principles which are universally acknowledged to be good are not innate principles.

I have heard it said that if you are not an artist (alas! what a cloak this term affords for the covering up of immorality) you are not obliged to visit galleries and museums and the various places where are exhibited the figures so offending to your eye. Quite so, but are not these publicly exhibited, and because they are places designed for public entertainment and improvement, are they not the very places that distinctly invite inspection of such figures?

I am a great lover of true art, and cannot justly be accused of having "no eye for the artistic," but if art is to produce such brazen-faced apologies for girls and women as are to be seen daily sketching from the nude at the museums, &c., I think the less said about art the better.—I am, sir, your very obedient servant,

RONALD KELLY.

16 Southampton Street, Fitzroy Square, W.:
July 31, 1897.

GENERAL.

The Treasury have appointed a committee to consider and report upon the desirability of establishing a national physical laboratory for the testing and verification of instruments for physical investigation, for the construction and preservation of standards of measurement and for other scientific and industrial purposes.

The Primitive Methodists have erected during the past year sixty additional chapel at a cost of 61,736*l.*, of which amount 35,854*l.* has been raised. The Connexion appears now to possess 4,743 chapels, which have cost 3,738,257*l.*, of which sum 2,642,990*l.* has already been raised. These chapels provide sitting accommodation for 1,003,625 persons, and the number of worshippers is 588,505.

Mr. H. Partridge has presented a convalescent home to the village of Bletchingley, Surrey.

An Aisle is to be added to the chapel of Wellington College as a memorial of the late Archbishop of Canterbury, who was the first head-master appointed by the governors.

M. Ch. Girault, the architect of the "petit palais" in the Champs-Élysées, and who acts as consulting architect for the "grand palais," has been nominated a chevalier of the Legion of Honour.

The Birmingham City Council have decided to erect baths at Small Heath which will cost 25,000*l.*; a sum of 29,000*l.* is to be spent on the widening of Bull Street, and two underground lavatories will be constructed at a cost of 4,000*l.* Holly Moor Farm is to be purchased for 10,000*l.* as a site for a lunatic asylum.

Mr. George Elkington, senior member of the firm of George Elkington & Son, died in Worthing a few days ago. He practised in the City as architect and surveyor for about half a century.

The Monument of the late Lord Arthur Hervey, Bishop of Bath and Wells, was unveiled in Wells Cathedral on Wednesday. The tomb was designed by Mr. Pearson, R.A., and the figure of the bishop is by Mr. Brock, R.A.

The Architect.

THE WEEK.

ONE of the difficulties of a London architect when working outside the Metropolis is so to deal with patronage as to give satisfaction to local expectations. There is a jealousy against London, and to bring work from London is to expose oneself to allegations of unfairness. An unfortunate case has just arisen in Glasgow in connection with the new art galleries. Sculpture is to be introduced into the building. The architects have recommended that the greater part of it should be intrusted to Mr. E. FRAMPTON, an artist who has already manifested his competence to treat architectural decoration; on the other hand, Glasgow possesses a school of art, and years ago sculpture was produced under the direction of its architects which will sustain a comparison with similar work in London. In such a case a heavy responsibility is cast on whoever introduces a stranger, for the northern clannishness has to be disregarded. But architects can have no higher guide than their conscience. It would be well if a compromise could be arranged, for Mr. FRAMPTON's appointment is a slur on local ability. We are afraid, too, that the outcry on the subject will oblige the authorities on future occasions to restrict their competitions to Glasgow architects. If Mr. FRAMPTON could make out some relationship with Scotland there would be less grumbling over the importation of his work.

COTTAGE homes for workhouse children are likely to be generally adopted throughout England since the Aston Board of Guardians (that is, Birmingham) has this week resolved to expend 50,000*l.* upon them. Originally it was contemplated to expend only half that sum, but on the suggestion of the Local Government Board the scheme was enlarged and the expense doubled. Sixteen homes are to be erected. As there are not more than 250 children in the workhouse the outlay will appear to be 200*l.* a child, but in reality it will not mean more than about 8*l.* per child per annum; or, in other words, 3*s.* a week for housing alone. As a workhouse exists the expense is an extra, but it is a concession to modern notions of duty, and the improvement in the character of the children is likely to be worth the outlay. Whatever may be the result, cottage homes are becoming an indispensable addition in all unions which are controlled by men who are inspired by modern ideas.

AMONG the papers read at the meeting of the Iron and Steel Institute in Cardiff was one contributed by Mr. G. C. HENNING, of New York. He discussed the necessity which exists for a portable recorder for testing metals. Testing machines are very big and very costly, but we suppose it is found to be feasible to devise one which, without having the accuracy of an instrument of precision, would be perfectly trustworthy, and as correct as the other apparatus in connection with which it is used. It should cover a wide range of work of short and long, large and small, test pieces, such as are found in general use, and be applicable to hard and soft materials as well. It should also be applicable in a horizontal as well as in a vertical position. Moreover, it should give a complete record from beginning to end of the test, showing the more important elements on an enlarged, and the lesser on a natural scale. With the use of such a recorder it would become instantly apparent whether material had been previously intentionally strained to raise the elastic limit, as is well known to have been done. Over-heating of material would be clearly indicated by the change in the curve, and the general uniformity of any lot of material could be readily determined. The instrument should also be applicable for compression tests so as to record the behaviour of material when subjected to compressive stresses. There never was a time when the need for testing was more urgent than at present. The figures that are put forth as the result of experiments on the strength of materials are often amazing. The official world for a long time declined to admit that

75,000 lbs. per inch was not an exaggeration of the ultimate strength of steel, but in America from 100,000 lbs. to 200,000 lbs. are accepted as ordinary representations of strength. As a consequence many engineers become dubious, and steel is sometimes supposed to be worth no more than a 20-ton breaking strain.

THE smoke nuisance afflicts some of the American cities. There are edicts against it, but the penalties are of such a nature which cannot be enforced. The chief smoke inspector in Chicago divides the inhabitants of that city into two classes:—(1) Those who create a smoke nuisance; (2) those who are compelled to tolerate a smoke nuisance. One class has radical champions, who maintain that smoke is an irrepressible necessity—a concomitant of the commercial and manufacturing supremacy of Chicago; that smoke not only is not unhealthy, but that it is an actual disinfectant; that the advocates of smoke abatement are visionary sentimentalists, and, in a general way, they are emphatically opposed to any agitation of the subject." The second class "declare that the smoke nuisance is a positive menace to the health of citizens; that it has resulted in an alarming increase in throat, lung and eye diseases; they point to ruined carpets, paintings, fabrics, the soot-besmeared façades of buildings and to a smoke-beclouded sky, and demand that the smoke inspector do his plain duty under the law." In Chicago there are more than 15,000 steam-boilers, 12,000 of which consume soft coal. These are distributed over an area of 186 square miles. The inspector says: "I know of an instance in which a restaurant firm so consumed 600 dols. worth of coal as to cause an actual damage to adjacent property exceeding 25,000 dols." He also cites "an apartment building, under the management of a receiver, protected by the court against the enforcement of the smoke ordinance," which, he states, "ruined the furniture and furnishings of every residence for two blocks in its neighbourhood, and depreciated the value of adjacent real estate more than one-third of its former value." Professor R. H. THURSTON, who is a recognised authority on engineering science, advocates a system of fines that would make the production of smoke more costly than its prevention. A fine of 25 to 50 cents a month per square foot of grate, he says, would be more than sufficient. He is supported by other scientific authorities.

CLAUSE 170 of the London Building Act of 1894 is one of the longest. It empowers the County Council, after obtaining a magistrate's order, to enter on premises where there is any contravention of the Act, to demolish or alter the building, remove and sell the materials, and recover any deficiency from the person committing the offence. A decision given by Mr. FRANCIS in the South-Western Police Court on Tuesday would make it appear that a change of ownership does not prevent the action of the County Council or diminish the liability. Mr. SCHIEFER, a builder, was in March last fined 10*s.* for erecting wooden structures at the rear of some mansions without the leave of the Council. As they were not removed, he was again summoned for the recovery of the cumulative penalties, but the summons was dismissed, because the Council had proceeded under the wrong section of the Act. A new summons under Section 170 was therefore taken out, and a magistrate's order empowering the Council to enter the premises and demolish the illegal structure and charge the defaulter with the expenses was sought. Defendant's counsel raised the plea that his client, having parted with the property since his conviction in March, had no longer control over the structures. The magistrate said the section of the Act was clearly intended to reach the premises without reference to the owner or occupier. Certain buildings were condemned, and the important thing was to demolish them. If the defendant would not do it, no question of ownership could stop the Council from carrying out the order of condemnation. A decision in favour of the Council with two guineas costs was given. On the application of the defendant's counsel, his worship agreed to grant a case for the consideration of a higher court.

THE GALLERY OF APOLLO IN THE LOUVRE.

ONE of the reasons which the President of the Royal Academy gave for his proposal to remove the Wallace collection to new buildings at Trafalgar Square was that a sort of gallery, corresponding with the Galerie d'Apollon in the Louvre, could be established with the help of the furniture. It is needless to say there is not much furniture in the Paris gallery, unless under that name we comprise the gilded cases which contain the treasures of the goldsmiths and miniaturists' art and the marble tables which are used as stands for caskets. But the gallery, although it is without any pictures, except the figures of artists high up on the walls and the ceiling paintings, is as entrancing as the Salon Carré. The visitor's attention by means of it is diverted from the duty of discriminating between various schools of art, and it would be an unquestionable advantage if something similar could be introduced in our National Gallery. At the same time it was well that the proposal was not adopted, for the Wallace collection is, all things considered, in its most fitting quarters in the mansion in Manchester Square. We may, however, be allowed to take the opportunity to consider the history of the beautiful gallery which was in Sir EDWARD POYNTER'S thoughts.

The majority of visitors to the Louvre do not realise that if ever a building could be considered as "a thing of shreds and patches," it is the great Palace of Art. Even with the aid of the numerous series of plans and drawings, it is difficult to imagine that for centuries there was no unity among the buildings, and that the existing dispositions would surprise any of the National Guards who fell in the contests of 1848. What is now known as the Galerie d'Apollon was subjected to as many modifications as any other part of the buildings. It is uncertain whether it was part of the additions undertaken by CATHERINE DE MEDICIS and attributed to her son; but apparently a gallery in that position was completed by HENRI IV. It replaced a terrace, and formed a part of a wing that was intended to form part of the royal apartments. By SAUVAL, two architects—PLAIN and FOURNIER—are said to have had charge of the works, but there is no other evidence of their existence. It is more likely that the gallery was among the extensive works directed by DU CERCEAU towards the close of the sixteenth century, and which were intended to form a residence that would not be connected with the old Louvre or with the Tuileries.

There is nothing to show that the gallery was originally dedicated to the Sun-god. But from the first it was adorned with paintings by BUNEL, PORBUS and BREUIL. Between the windows were full-sized figures of the kings of France from SAINT LOUIS to HENRI IV., with their wives. In order to insure accurate likenesses BUNEL and his wife travelled through France in search of contemporary portraits, costumes and details. The portraits were not confined to the rulers. There were also busts of the men who were distinguished in the different reigns. In that way was created a characteristic of the Louvre, for the outside now displays so many portrait statues, it has more claim to be considered as a dedication to the *grands hommes* of France than the Panthéon itself. The designs for the ceiling paintings were entrusted to BREUIL. Some subjects were derived from the Old Testament, others from mythology. The artists all belonged to the school of Fontainebleau, and the slightest engraving from their works would be invaluable as suggesting whether there was any progress among French painters. But no provision of that kind was made, and in 1661 the pictures were destroyed by a fire, which injured other parts of the aisle containing the gallery.

LOUIS XIV. was desirous to have the gallery restored, and entrusted the task to LE BRUN. That artist could adopt his master's words and say, "L'Art c'est moi!" He made sculpture subject to painting. The figures which were lavishly introduced were designed by him, and executed by GIRARDON and three other sculptors. The king offered a premium of 300 louis to whoever among them was most successful, and the choice fell on GIRARDON. The ceiling paintings and panels on the walls were undertaken by LE BRUN, but were never completed. Out of compliment to LOUIS XIV., the "Roi-Soleil," on the ceiling he proposed to paint APOLLO in his chariot, surrounded by figures of the Seasons, Aurora, Muses, &c. That

was the central composition. At the extremity was a scene representing Night, and the corresponding position was filled with a *Triumph of Amphitrite*. The last alone was completed by LE BRUN.

The death of the painter and the financial embarrassments of the king suspended the operations. The unfinished gallery was ill-adapted for state ceremonies, and was employed for exhibitions. LE BRUN'S pictures were hung there. Then a collection of casts from the antique was placed in it for the benefit of students of the Academy. The next step was to break it up into ateliers. It remained in a degraded state for over seventy years. In 1764 it was resolved to do something towards the restoration of the gallery. There were new ideas about economy prevailing, and it was supposed the decoration could be accomplished without the cost of a sou to the State. The French Academicians were under an obligation to present a painting on their election. By compelling each of them to fill one of the compartments of the ceiling or a panel, the rule of the Academy about diploma works would be observed, and in course of time the vacant spaces in the gallery would be embellished. The process was slow, for Academicians were not elected every year. In seventeen years only four "cartouches" were obtained.

During the revolutionary tempests and the Imperial wars which followed, the state of the Galerie d'Apollon excited little commiseration. It served for the Salon exhibitions, which sometimes did not continue for a month. Owing to the dampness, the plaster figures and ornaments gradually decayed and the subjects of the paintings were recognised with difficulty. The roof suffered most. In 1826 it was decided to construct a new one in wood, care being taken to preserve, where practicable, the sculptured and painted decoration. Under the direction of FONTAINE the difficult work was carried out with success.

In 1848 another restoration was commenced under the direction of DUBAN, the architect. EUGÈNE DELACROIX agreed to paint the central work of the ceiling, the subject being APOLLO slaying the python, and he produced one of his most characteristic works. No ceiling painting executed during the century surpasses it, and one can hardly believe that LE BRUN'S work, which was intended for the same position, would have approached it in effect. CHARLES MULLER painted an *Aurora* partly from a sketch by LE BRUN. There are on the ceiling some compartments by eighteenth-century painters, and the whole gallery is worthy of a royal palace.

It would be possible, by levying contributions on the South Kensington and the British Museums, to bring together collections that would look as well as those found in the Gallery of Apollo. There would of course be one great deficiency, as we could not have a display of Crown jewels, but that need not excite much regret. What we dare not hope to have would be the casket of the treasures—that is, the glorious room which seems to exemplify French decoration in its most grandiose form. Unless the walls and ceiling were as beautiful as those of the Louvre the Trafalgar Square gallery would be a disappointment. It would be a victory to be able to compete with the French, but as regards their Galerie d'Apollon, we must remain behind them at a respectful distance.

ASBESTOS.*

THE qualities of asbestos were exactly of the kind which were likely to excite amazement in a primitive or an ignorant age. Men felt themselves compelled to submit to nature as an unknown power that was omnipotent and not disposed to mercy. They did not dare to arrogate to themselves any competence to become its interpreter. But they felt satisfaction when they discovered that nature could have failings like themselves. Hence the fascination of *lusus nature*. Asbestos might be classed with them. To have a material resembling tow, silk or thread amidst the hardest rocks suggested a departure from nature's ordinary course, and one that was unsuccessful. For asbestos must at all times have suggested something that was commenced but never completed, an immature transformation—

* *Asbestos and Asbestic*. By Robert H. Jones, F.S.A. London: Crosby Lockwood & Son.

in one word, a freak. When the discovery was made that, light and flossy as was the stuff, it resisted man's most terrible enemy, fire, and in that quality was almost unique, we might expect that it would receive the honour belonging to a great protector. But the scarcity of the material, and the difficulty of manipulating it, so far restricted its use that it could not be considered as worth classifying among beneficial things. A chief or a rich man might have the satisfaction of considering that his ashes or his corpse would be preserved in a piece of stuff that was made from the material, but they must have been loyal followers who could take a personal interest in a post-mortem privilege of the sort. It was easy to use the filaments for wicks, and by that means some of the so-called inextinguishable lamps of the temples may have been produced. The ancient magicians may also have employed asbestos as a deceptive agent. But, as well as can be made out, the early applications of the material were limited, and if judged by modern notions, were unimportant.

The earliest account of asbestos which is based on observation is found in MARCO POLO's travels. The following information was given on the authority of a Turk named CURCIFAR, when speaking of the products of the Province of Camul:—"In this province there is a mountain where are mines of steele and audanicum, and also salamanders, of which cloth is made, which if it be cast in the fire cannot be burned. A certaine minerall of earth is found in that mountain, which yieldeth threads not unlike to wooll, which, being dried in the sunne, are bruised in a brazen mortar and afterwards washed, and whatsoever earthy substance cleaveth unto them is taken away; lastly, those threads so purged and made small are spunne, like other wooll, and woven into cloth. And when they will whiten those clothes, they cast into the fire for an houre, and then they are taken out of the flaming fire unhurt, whiter than snow. After the like manner they cleanse them when they have taken any spots; for no other washing is added to them besides the fire."

As a contrast to the thirteenth-century practice which MARCO POLO describes, we give Mr. JONES's account of the process now followed in the works of the United Asbestos Company, Limited:—

The crude asbestos, when extracted from the mines in rock-like blocks of fibre, is packed up in bags containing from one to two hundred weight each, which bags are brought over to England, and discharged into lighters in the Thames, whence they are conveyed, by way of the Grand Junction Canal, to the Company's works at Harefield, in Hertfordshire. Here the bags, on being opened, are found to contain the asbestos in rough lumps, from the size of a man's head to about as much as one man can lift. And here all classes of asbestos goods are manufactured in the several forms in which they are now offered to engineers and others.

The company's works are divided into several departments. First, there is the sorting and opening department, where the crude asbestos is dealt with. The blocks of fibre or "rock" are crushed, and opened up by special machines, in such a way as to loosen, without destroying, the fibre, but rather to free it from the material which compactly binds it together, and which, it will be observed, has no counterpart in the method of dealing with Canadian ore. The masses of fibre are passed thence to "shaking" machines, where the long fibre is separated from the short, and all particles of rock removed. The long fibre, suitable for spinning into thread, is then taken into the carding, and the short to the millboard and boiler-covering departments. The tanks here are each provided with a rotating beater, which maintains a thorough circulation by first taking up the fibre, then opening and drawing it out, and afterwards sending it on to be soaked, until it comes round again to the beater. The treatment of the long fibre in the carding and condensing department is very similar to that in a textile factory, but its appearance would be scarcely encouraging to one who had been accustomed to the weaving of cotton or wool alone. These latter staples, examined under the microscope, exhibit a notched, serrated or imbricated appearance, which explains the readiness with which these difficulties are overcome by special appliances attached to the condensing machines. As the fibre comes from the condenser in the form of silver or condensed thread, without any twist, it lightly folds itself in cans placed there to receive it, and is then taken to the spinning and doubling department, where it is twisted into threads of every degree of fineness required. The thread then passes to the weaving and braiding department, where it is made into various forms of yarn packings, tapes and cloth. The cloth is then taken to the indiarubber department, where

it is proofed, and made into what is known as asbestos and indiarubber woven sheathing, tape and rings for steam and other joints, as well as into rolled cloth and square block packings for glands.

The short fibre, reduced to fluff, is taken to edge-runners and ground, and prepared for the beating engines, where the binding material is added and the whole thoroughly incorporated, after which it is drawn into a receiving tank and placed in the millboard machine-room. From this tank it is conveyed to the millboard machine, to which agitators are attached to keep the fibre from settling. The water is drawn off, through a fine wire gauze, on a revolving cylinder, on which it leaves a thin coating of the asbestos pulp. This is then taken off by an endless band and transferred to a second solid rotating cylinder, where it steadily accumulates till the desired thickness has been reached. It is finally cut across and removed in the form of a square sheet of millboard or paper.

The old asbestos-weavers of Camul would be amazed at the long series of operations to which the material is subjected. But more mysterious would appear the uses to which it can be converted. Following the order in Mr. JONES's book, we find asbestos employed as packing for machinery, millboard, gasket, rubber-cloth sheeting, boiler and pipe coverings, lining of furnaces, fire felt, felt for flues, breechings, bulkheads, quiltings for boilers, coverings for boiler-tops, &c., sponge for protection against freezing in pipes, electrotherms for households and hospitals, electric heat pads, electric car heating, insulating, asbestos packed side bars, closing breeches of big guns, miners' lamps, coating for ironclads, torpedoes, time-fuses, dynamite shells, military aeronautics, stove-pipe shields for tents, awnings for waggons, safes and deed-boxes, carriage of explosives, lint, hospital purposes, &c. For many of these purposes other materials are combined with asbestos, but unquestionably it imparts to them the qualities which are most prized in the market.

The employment of asbestos in connection with building is manifold, especially in the United States and Canada. One American company produces from two to four miles of asbestos roofing daily. It consists of "a strong canvas, combined with a superior quality of felt, made expressly for the purpose, with a manilla lining or backing; these materials are rendered waterproof and cemented together with a special acid and waterproof composition, and compressed into a compact flexible sheet like leather." The felt is also employed for lining weatherboarding, partitions, &c., and as sheathing. One of the building laws of New York orders that in theatres "the proscenium opening shall be provided with a fireproof metal curtain, or a curtain of asbestos or similar fireproof material," thus placing asbestos on the same level as metal for safety. In Philadelphia the underwriters offered to reduce the premium on the Academy of Music if an asbestos curtain was introduced. All the theatres in Rome are provided with them. One of the Brussels theatres has been coated with a mixture of asbestos and alum in order to render it incombustible. Mr. JONES is confident that in the United States "the use of asbestos in some form or other will be made compulsory for the shelvings and doors of public libraries and places for the custody of records, for sheathings between wooden floorings and below carpets, for hearthstones, for the linings of doors of elevators or lifts, for elevator shafts or stairways, and for the innumerable other places exposed to danger from flame or intense heat."

Can it be assumed that the supply will be equal to the demand? Asbestos is limited in quantity, but as it is likely to be found wherever there are serpentine rocks, there need be no apprehension of a deficiency for many years to come. At present Italy and Canada are the chief productive regions. There is serpentine in the United Kingdom: unfortunately, the asbestos that should accompany it is so limited as to be without economic value. Ireland seems to be doomed to immaturity. The bogs are full of premature coal, and the serpentines in Mayo, although so beautifully marked as to be fit for decorative purposes if they were brought to London, cannot tempt speculators in asbestos. Mr. JONES, as a specialist, was sent over to examine the veins, but found them only tantalising. He tells us how he found "such abundant indications as proved ample justification for the expectations which had been raised, but nowhere, unfortunately for the inhabitants of that poverty-stricken

district, could one be justified in recommending any great outlay to be incurred in the hope of attaining any favourable result." It is some consolation to know that Canada, Newfoundland, South Australia and New South Wales can yield supplies, and in the British possessions in Africa asbestos is also likely to be found.

The wonderful success of the Danville Mine, near Quebec, is moreover enough to encourage investigation, for there a material now known as asbestic has been discovered, which serves as well as asbestos for some purposes. The former owner of the property suffered through want of money while a fortune was under his feet. After the closing of the mine, a Mr. BOAS was invited to make an effort to utilise the property. Mr. JONES, when at the mines, estimated that "the whole mass contained, at least, 90 per cent. of good merchantable asbestos or asbestic," and, in fact, all that used to be considered waste can be utilised.

The volume by Mr. JONES is the work of a gentleman who has studied the phenomena connected with asbestos in most parts of the world. His descriptions being derived from what he saw are most vivid, and it is no exaggeration to say that although his pages are inspired by the sober spirit required in treating of business subjects, they are no less fascinating than those which have immortalised HUGH MILLER. "Asbestos and Asbestic" is a geological romance, while serving as a guide to financiers and speculators.

ELECTRIC WIRING.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

LOOKING back to the early days of electric lighting, it must be noticed that the progress made in the methods of wiring used have not been so great as in other branches of the industry. The reasons for this are easily found. Most of the profession have been engaged with the more interesting portions of the subject, and the engineers who have been engaged in the wiring business have usually not had the time to devote to improvements. They have been content with wood casing for years; no real improvements having been suggested until about three years ago. About this time the interest in the subject of wiring revived, and the only people who now lag behind are the fire insurance inspectors, these gentlemen; however, are usually not electrical engineers, although they criticise any new system submitted to them.

In the early days the wires were either fastened to the walls by staples or saddles, or embedded directly in the plaster. This reminds one more of electric-bell work than of electrical engineering; it is, in fact, unmechanical as well as defective electrically.

Another system in use, chiefly on the Continent, is to fix small insulators into the walls, fixing flexible cord to these by splitting the twisted wires and springing them over the insulators. In other cases bare wires are bound to insulators, and in others ordinary insulated wires are fixed to them. These systems are, in England, usually confined to factories, &c., where appearances need not be studied, and are omitted here, as buildings of a more ornamental character will be considered only.

The next step was that of cleating wires to the walls, and this was followed by a continuous cleating, that is, casing. This is the method now so generally used of running the wires in a wooden moulding fastened to the walls, and has been in use for many years, but it has been recognised by electrical engineers that it is not all that could be desired.

This is the first system that will be considered in detail, but it would be advantageous to formulate the conditions which a perfect system of wiring should comply with before doing so:—

1. Safety from fire risk.
2. Good protection for wires.
3. Accessibility.
4. Impossibility of inferior work.
5. High electrical insulation.
6. Low cost.
7. Ease of extension.
8. Good appearance.

It is practically impossible (at the present time) to

name a system which will comply with all these conditions, but the various systems can be compared with the standard. It must, however, be borne in mind that no one system is suitable for every case; local conditions must be fully considered.

It is a fact that if special care is taken a wood-casing system may be carried out so that the fire risk is negligible, but if any carelessness is allowed there is no doubt that the fire risk may be heavy. Let us consider the materials. An indiarubber covered wire (inflammable) enclosed in a wood casing which the insurance companies direct to be shel-laced, avowedly to keep the damp out, but which practically increases the inflammability. It is impossible for a nail to be driven through both wires, so a short circuit will not be developed, but an earth. The insurance companies insist that the wires shall be separated from each other, with the idea of preventing a short circuit. If there is an earth on one pole of the installation, and assuming a little damp, the wire will be gradually electrolysed and corroded until two fine points are made, when it is eaten through. The current passing along the wire arcs between these, dries the casing and causes a fire. If the wires were not separated both would be earthed together, the fuses would go, the circuit be entirely disconnected, and attention drawn to the matter.

Wood casing is a fair mechanical protection, but there is a great temptation to drive nails for pictures, &c., into it, owing to the difficulty in getting a nail to hold in ordinary walls. It is not, of course, waterproof. The chief point urged for wood casing is that it is accessible; but even in surface work the capping, if taken off, cannot as a rule be replaced neatly owing to the bunching of wires. When buried in plaster, as is usually the case, the wires are really inaccessible without damaging the decorations.

With regard to the possibility of inferior work this is rather high. Even with surface work the wires and joints are seldom seen when the work is being carried out, and it is not practicable to remove all the capping afterwards, so only certain places are taken. The quality of the work cannot be tested by taking the insulation resistance on completion. In one case which came under the notice of the writer, the fillet of the casing was cut away to within one-eighth inch to make room for bunched wires; this is contrary to the rules under which the work was carried out, yet it was only by chance that it was discovered. Joints are often made so that they are not water-tight, and conductors are frequently of less section than specified. Where conductors pass through walls they are seldom run through porcelain tubes; usually they are put in "compo" pipe, and more often are left unprotected entirely. Again, the safety of the work depends upon the class of insulation used, as the casing is not waterproof, but it is impossible for anyone but an expert to tell the class of wire, even if he has a sample. The thickness of the insulation is practically no guide.

The insulation of this system should be fairly high, but it is determined more by the surface leakage over the porcelain fittings than by the insulation of the wires.

The first cost in houses, and, in fact, any place where neatness is desired, and where the length of wire and casing is great in proportion to the number of points, must be high, owing to the labour charges.

The system is generally inextensible unless new casing is put up, as fresh wires cannot be laid in the same unless allowance has been made for this.

The appearance of the system is of course unobjectionable if the casing is buried, and the surface work may look neat or otherwise, depending on the kind of decorations or the skill of the workmen.

We have now seen the objections to and the faults of wood casing, and will go into the systems devised for the purpose of improving upon it.

One system is that of employing iron barrel for drawing the wires into. This conduit is similar to gas-pipes: iron junction-boxes, &c., are made, and the wires are drawn in the last thing, when the decorative work is finished. This system is being largely used for the higher-class work in London.

Another and somewhat similar system is that which has been used in America for some time, and is now being introduced here as the interior conduit system.

The conduit consists essentially of bitumenised paper tubes, connected together by metal joints in a manner which is watertight. These paper tubes are buried in the plaster; joint-boxes and special blocks are provided; the wires, as in the iron barrel system, being drawn in later. These paper tubes are sometimes armoured with brass sheathing and sometimes are placed inside iron barrel.

High-class cables and wires are used in the plain iron barrel system, and wires with thin insulation in the interior conduits.

Both these systems must be taken on a higher level in every way than wood casing, and the fire risk is very low. Both wires being in one tube (the wires being often twin), it is practically impossible to injure one wire without the other, as a short circuit is produced which immediately blows the fuse and disconnects the circuit. It is very difficult to see any objection to the iron barrel system, or to the iron armoured interior conduit, as they are gas, water and fireproof; any arc in the pipe will hardly produce sufficient heat before the fuse blows to ignite even the most inflammable material surrounding the pipe.

The protection for the wires in the iron conduit is perfect, while in the paper interior conduit it is quite as good as wood casing. There is some danger of damaging the wires with the iron barrel system, especially during drawing in, and the insides of the pipes should be rymered out before being used, and with careful drawing in any serious damage may be avoided.

There is perfect accessibility; any wire can be drawn out without removing anything but the lid of a junction-box and perhaps a fitting or two.

There is much less liability to bad work with these systems than with wood casing, and any bad joints in the pipes, &c., can be found by a simple air-pressure test, preferably before plastering. All joints in wires are in junction-boxes or fittings, and can thus be examined easily. This is a great point in its favour. The great disadvantage of the system is the want of flexibility of the conduits, &c. The insulation resistance will be about the same as with wood casing. The first cost is high, being from 50 per cent. to 5 per cent. above that of wood casing, and if the tubes are put in fairly large to commence with extra wires can easily be drawn in. The appearance of any of these systems would be very bad for surface work, but they are primarily intended for buried work.

A modification of the iron barrel system for surface work in highly-decorated rooms, &c., is that in which brass tubes are substituted for iron barrel. These are placed under the cornices, and are also used as picture rails. Very neat and effective work may be done in this way.

There is an iron-armoured system which is not a conduit system, viz. the concentric, in which rubber-covered wire armoured with iron wires is fixed up to the walls, the iron armouring serving as the earth return. This system has met with some success, and its advantages are somewhat similar to the concentric system. It is, in fact, the connecting link between the conduit and the lead-covered systems, which will next be dealt with.

The lead-covered systems have one thing in common. In every case the two conductors are enclosed in one continuous lead sheathing, which is watertight and flexible. The conductors are in some cases arranged concentrically and in others they are twin.

The first used system of this class was the concentric, earthed outer. Here the inner conductor is insulated with jute impregnated with a resinous insulation. The outer conductor consists of copper strands, on which is pressed a continuous lead covering. The iron-armoured concentric mentioned above differs from this in the fact that the lead-covered is watertight and the iron-armoured is not.

Special concentric fittings, switches and lampholders are used with both systems, the idea being that the insulated conductor shall always, even in switches, be surrounded entirely by the outer earthed one. Iron armouring is sometimes stranded over the lead in the latter system where the wire is exposed to mechanical damage.

The fire risk is reduced to a minimum with this system. Any fault in the inner wire *must* develop a short circuit, blowing the fuse long before a fire can be caused. There must be gross carelessness in erection if any combination of circumstances can cause a fire. Of course, if the fuses are

replaced by thick copper wires, and if the joints are made badly, a fire may be caused, in the latter case by electrolysis of the outer wire and its subsequent destruction causing arcing; but these are practically the only points to be guarded against.

With regard to accessibility, this is the chief fault, as the appearance of the joint boxes, &c., is against the system for surface work. If buried in the walls, the wires and, worse still, the joints are inaccessible.

The protection for the wires is good in the case of armoured, and as good as wood casing in the plain lead-covered wire. The possibility of bad work is, I should think, about the same as with a conduit system. The insulation is high, and the cost does not exceed that of wood casing by more than 15 per cent., and this is due to the cost of special fittings which are patented. There are no facilities for extension, and with regard to appearances, although the wires are themselves not so unsightly, the joints and special fittings are very objectionable; but, if buried, most of these objections disappear. The great disadvantage is that with such a system the outer conductor *must* be earthed, otherwise the method of jointing falls to the ground and the wires become bulky. The flexibility of the wire is certainly one of the chief advantages of the system.

A system somewhat on the same lines, but adapted for working on public supply circuits is the twin-wire lead-covered system. The twin wire is arranged so that it is very small (the branch $2\frac{1}{2}$ -ampère wires being only a quarter of an inch in diameter); being paper insulated, it is mechanically strong. The cheapness of this wire and the low cost of fixing enables it to compete successfully with any other system, and there is no doubt of the permanency and efficiency of the work. The lead covering is sweated into solder bases for switches, ceiling roses, &c., the ordinary fittings being screwed to these blocks, the whole is made water-tight by means of rubber rings, or a form of small end connection, &c., may be used. When joints are made the lead coverings are wiped as a plumber would make a joint in a water-pipe, but it is better for all joints to be at the distribution board or in switches, &c.

It will be seen that as no conductor is earthed the system can be generally applied, and as it is much cheaper than wood casing it will come into general use. The general advantages and disadvantages of this system are similar to those of the concentric. With this system it may be preferable to use a concentric cable for the larger mains.

No one system is suitable for every circumstance, and this must not be lost sight of when choosing the system. The iron conduit has many advantages for buried work, leaving out consideration of expense.

Having now gone into several systems of wiring, it may be well to take two cases, viz. that of a new building and an old one.

In the case of a new building it is to be regretted that the lighting is generally left until the building is nearly completed. The architect then naturally does not feel disposed to have his walls and decorations pulled to pieces, with the result that a surface system is adopted. If the matter had been settled earlier not a wire need be seen, conduits or pipes being run in a manner similar to that for gas and water-work. The wires need not be drawn into these conduits until the building is completed, thus obviating any injury to them or inconvenience to workmen.

If, on the other hand, a highly decorated building which is not new is to be illuminated, it requires a very considerable amount of skill and consideration to work in wood casing or moulding with the surroundings, but if done carefully a very good effect may be obtained. Brass tubing of small size (already mentioned) may often be adopted with advantage for the branches, being run under the cornices without the least reason for complaint as to unsightliness, the mains being run in iron barrel, or with concentric mains twin lead-covered branches may be used, either painted to match the surroundings, or with a brass fluting as a cover, or it may be covered by a wood moulding.

Sir J. Blundell Maple has offered to advance 3,000*l.* for the erection of club buildings in the grounds of the Royal Botanic Society.

DEPARTMENTAL MUSEUMS.

THE select committee appointed to inquire and report upon the administration and cost of the museums of the Science and Art Department have agreed to the following second report:—

Your committee have met twenty-seven times, and have examined witnesses, including Earl Spencer, a former Lord President, the Earl of Carlisle, trustee of the National Gallery and art referee in connection with the Science and Art Department, Sir Edward Maunde Thompson, Principal Librarian of the British Museum, the Secretary of the Science and Art Department, the Directors of the South Kensington and Jermyn Street Museums, the Director for Art at South Kensington, and also the Directors of the Edinburgh and Dublin Museums. Your committee have, by the death of Mr. Mundella, which they deeply regret both on public and private grounds, lost the advantage of the evidence which he was about to give to the committee on the subject of their inquiry. They have been unable to complete the inquiry in the course of the present session. They feel bound, however, to confirm and emphasise the recommendation of their first report as to the necessity of immediate action to secure the buildings against fire; and to express their sense of the importance of completing the building on the east side of Exhibition Road, with a view to the safe deposit and satisfactory exhibition of the art collections (including the Indian section now on the west side of the road in a hired building) at South Kensington. These collections are, in the opinion of the most competent authorities, of immense value in themselves, and increasingly fulfil the great national purposes for the promotion of which they have been brought together. Your committee have agreed to report the minutes of evidence taken before them, together with an appendix, and to recommend that the committee be reappointed at the beginning of the next session of Parliament.

BRITISH ART AT THE BRUSSELS EXHIBITION.

THE honorary secretary of the British Fine Art section of the Brussels Exhibition writes:—

It is probable that the significance of the awards made to British artists in the section devoted to the fine arts at the Brussels International Exhibition has not yet been fully realised in England, and I shall be glad if you will permit me through the medium of your columns to make a few observations to show what the results really mean. To do this it is necessary to compare the awards with those achieved by other countries, both as regards their number and the relationship of the number to the number of the exhibits.

In the class devoted to painting three Médailles d'Honneur were given, and of these one has been taken by England, one by France, and one by Belgium. Nineteen other medals have been awarded to British artists (eight first class and eleven second class), as against seventeen to French artists (eight first and nine second), twenty-one to Belgian artists (nine first and twelve second), eight to Dutch artists (three first and five second), and three to Italian artists (one first and two second).

If these figures be compared with the number of pictures contributed—Great Britain 315, France 435, Belgium 503, Holland 216, and Italy 69—it will be found that Great Britain has taken one award in every 16 pictures exhibited, France one in every 24, Belgium one in every 23, Holland one in every 27, and Italy one in every 23 pictures.

In sculpture Great Britain contributes but 22 works and has obtained three medals—*i.e.* one in seven exhibits; France has 86 works and obtained 12 medals, or one in seven exhibits, and Holland contributed 23 works and has been awarded three medals, or one in seven exhibits.

In the sections of engraving and architecture Great Britain has taken but one second-class medal in each, but in these arts we have been, as we expected to be, completely out-classed.

It will be noted that first and second class medals only have been awarded at this exhibition, third-class medals and honourable mentions usually given at international exhibitions having in the present case been abolished. Hence the comparatively few awards are of greater value; though, on the other hand, considerable injustice is done to many artists in an exhibition such as ours of a high level of excellence. To say of two works of nearly equal merit that one is worthy of a second-class medal and the other nothing at all is at once misleading and oppressive.

I am anxious to lay stress upon the fact, nevertheless, that these satisfactory results as regards the British section have been obtained in spite of the fact that many of the most attractive works are by artists now deceased, and that upwards of eight other leading painters have withheld their works from competition—all of them being thus disqualified from the award of medals. Otherwise it cannot be doubted that a still larger number of honours would have been awarded in our section.

Owing to the fact also that four other important exhibitions in England and on the Continent were being promoted at the same time as that at Brussels many of the finest English works were unavailable. These gratifying results, too, it may be added, were obtained notwithstanding that England—owing to the brief notice given by the Belgian authorities—was represented by only one vote upon the international jury and one voice in the proceedings to press forward English interests.

TESSERÆ.

English Village Churches.

IT must not be imagined that it is only in great abbeys and cathedrals that the thirteenth century was fertile. On the contrary, little village churches in all parts of the land illustrate the same possession of power on the part of the country architect or mason that we see in those who built the former. There are no examples more interesting than these, whether we take the Sussex village church, with its intensely simple lancet windows, its coved wooden roof, and its shingle spire; or whether the Northamptonshire churches, built of good stone, with much rich decoration in their detail, and adorned with towers and spires, which are the pride of the whole country; in all will be found the same extraordinary equality in detail and harmony in character. They bring before us the especial glory of England—the small village church—in perfection; and there is one feature in them which one may almost say is unsurpassed elsewhere. This is the steeple. Usually it is placed at the west end of the church, and surmounted by a spire. The outline of this is always of the most severe kind; an octagon placed on the square tower, with very simple spire-lights on the cardinal sides only, and a steep slope, and sometimes small pinnacles connecting the octagonal base of the spire with the square outline of the tower. Here, as in most works of the period, the effort seems to have been to obtain as simple and graceful an outline as possible, and to construct the work so that there should be as few elements of decay in it as might be. In later times, though the early broach spire was sometimes copied, it was much more usual to add parapets, flying buttresses and complicated pinnacles at the base of the spire, and thus at the same time to destroy the simplicity and diminish the stability of the work. The history of our village churches is of course involved in much more obscurity than is that of our cathedrals. We know but little indeed as to the architects or the builders of the latter, but nothing at all as to those of the former. And though an occasional reference may be found to some one man now and then in Italy, Spain and France, it is after all only a conjectural result at which one can arrive as to their condition or character.

The Interior of Milan Cathedral.

The first particulars which strike one on passing to the interior are that it is dark and gloomy, and that the leading lines are very much interrupted by the shrines introduced in the capitals of the piers, which injure also the apparent solidity of the building. And when we are told that it is nearly 500 feet long, 180 feet wide and 150 feet high, we can hardly believe it. Indeed, as to the last dimension one remains incredulous; for whether we estimate the height by a general comparison with the other dimensions, or from summing up the estimated heights of the different parts which compose it, or from counting the steps which lead to the outside and measuring some of them, it seems to fall short of 140; and it is necessary to be aware that the side aisles are 96 feet in height to be reconciled even to that supposition. To what we are to attribute this want of apparent magnitude is uncertain; the height of the side aisles certainly diminishes the appearance of that of the nave, but the width of the nave is not remarkably great in proportion to the other dimensions. At Amiens this is 45 feet 6 inches. In York, our largest cathedral, it is 47; here it is about 55. With all these defects, however, it is impossible not to acknowledge the sublime effect of the interior. The style does not correspond with any of our English modes of pointed architecture. The vaulting is simple, without any branching ribs or any ridge piece; it is so much supervaulted that each bay appears to be the portion of a dome; and the disposition of the materials in concentric circles, or in portions of such circles, makes one believe that this is nearly the case. The windows of the clerestory are extremely small and insignificant; those of the side aisles are long and narrow. They are ornamented with quatrefoils; but a division of the height into two parts by arched ribs, which have not precisely the effect of transoms because they do not cross the window at the same level, indicate a very different period of taste from that of the rose and quatrefoil heads in France and England. The lower part of the capitals has something of the running foliage of the fourteenth century in England; but the shrine-work which forms the upper part is

perfectly unique. The bases and the plans of the pillars are equally anomalous, and any person would be baffled in attempting to determine the date from the architecture; only he might safely decide that it could not be very early. The smallness of the upper windows produces a gloomy appearance and oppressive feeling, like that of the cavern style of architecture in the south of France, with which it has nothing else in common. The height of 78 feet, which is that of the lower range of aisles, seems, indeed, to give plenty of room for the admission of an ample quantity of light from this part alone, but such a disposition seldom produces a pleasing effect. There are three fine large windows in the polygonal end of the choir, but even these are ill-placed and have little effect.

The Archbishop's Chapel, Ravenna.

Noblest among specimens of fifth century work at Ravenna are the mosaics in the chapel built by St. Peter Chrysologus about A.D. 440, in the archiepiscopal palace. This palace is itself a curiosity, and one of its great halls contains a valuable museum of local antiquities, Christian and Pagan, mostly monumental; among the former series a fine apostle's head in mosaic, and some rich inlaid pavement from the now, alas! vanished cathedral. It is from this antiquarian treasury that we pass into the beautiful chapel, in plan like the letter T; and as we first distinguish by dim light the solemn figures and sternly expressive heads, the large-winged angels and sacred symbols on the golden groundwork of storied walls and vaults, the mind is possessed by a sense of the majesty of the ancient Church and her sacramental mysteries. We seem to have left behind the glare and follies of the world in crossing this threshold. Above a marble incrustation round the lower parts expands that field of mosaics in brilliant hues unfaded, as the quaint and massive architecture is alike intact, since the days when the emperors of a ruined state trifled away their fear-stricken lives at Ravenna. The Saviour is everywhere conspicuous and central here, represented as at different ages, but always at once recognisable. We see Him as a boy, with the twelve Apostles in a series of medallion heads; we see Him again as a youth of about eighteen years; with the same benignly beautiful features more developed; and again as a fully-matured man, still in mind and noble-looking, in costume like that of a Greek emperor, with tunic of gold tissue, purple chlamys with jewelled clasp at the right shoulder, in one hand a long red cross, in the other a volume open at the words of most blessed assurance:—"Ego sum Via, Veritas et Vita." His head alone among all here before us is crowned by the nimbus, and striking indeed is the superiority, the majestic benignity that distinguishes the Divine subject as here conceived by art compared with the repulsive aspect given to its form in another mosaic treatment of the same year, 440, at the Ostian Basilica, near Rome. On the vaults of this venerable chapel are the usual winged symbols of the evangelists, each with a jewelled book, and at the centre the holy monogram in a disc, supported on the uplifted arms of four angels—majestic creatures in long white vestments, whose solemn countenances express a kind of awful joy. The numerous other figures and heads of apostles and saints are characterised by general sameness of type, with eyes large and staring, forehead low and flat, lips full, the female heads all veiled, but with rich coiffure and braided hair in sight, except St. Felicitas, who has the head-dress of a nun. SS. Peter and Paul display the well-known types with which one is familiar even from the period of catacomb art. Over the altar is the only mosaic here of later date than the rest, one from the lost cathedral (twelfth century), representing the Blessed Virgin in act of prayer, with outspread arms, the head closely veiled, the figure in long purple robes, the aspect that of matron maturity, modest, severe—the unmistakable character here intended, that of the interceding mother, or rather the personified Church.

The Column of Phocas in the Roman Forum.

When the sunset-light gilds the ruins of the Roman Forum the eye is arrested by that lone column that stands isolate amidst statelier relics, and the Classic style of whose shaft and capital strangely contrasts with the rudeness of the plinth and basement raised on a quadrangular staircase; this being the monument that had so puzzled archaeologists before the disencumbering (1813) of its lower part from the soil in which it had been deeply embedded, brought to light the mutilated inscription on its plinth that records its dedication to a Greek emperor, not by Senate and people, but by Smaragdus, Exarch of Ravenna, Patrician of Rome, and Prepositus (or major-domo) of the Imperial Palace, who erected this column, A.D. 608, in honour of the despot Phocas, whose gilt bronze statue stood at its summit. That usurper had opened his way to the throne by the deliberate murder of Mauricius, his unfortunate predecessor, who was actually slain in his presence on the mangled bodies of his five sons, one an infant, put to death before their father's eyes. To this wretch is ascribed every imaginable virtue in the eulogistic epigraph; but, for the honour of humanity, it is satisfactory to know that not only was his statue cast down from

this column after his death, but his epithets of adulation—"optimo, clementissimo, piissimo, &c."—were partially erased, and the mention of that bronze image entirely so, from the inscription; so that, but for the name of Smaragdus, and the date by the year of indiction still to be read, this monument would be without any mark serving for historic identification. Phocas lost his throne and his life by revolution and assassination not long after his last detestable crime in ordering the widow and three daughters of Mauricius to be put to death, though he had given promise to the Byzantine patriarch to leave them unmolested in the convent where they had taken refuge. The memorial to such a ruler serves not only to perpetuate his guilt but to attest the moral degradation of the age and social state in which it could be erected.

Points of View.

If unity of point of view be a *sine quâ non* in a picture, how comes it that we allow a scene—depicted according to the laws of perspective, of light and of effect—to be so placed that the spectator is forced to look at it from a position 4 or 5 yards below its horizon, and possibly a long way to the right or left of this correct point? This has to be tolerated whenever monumental painting makes use of the processes proper for easel pictures. In the great epochs of art such enormities were forbidden. During the Middle Ages, in pictures painted upon walls at all kinds of elevations, painters never took into account either horizon, locality, effects of perspective or the rigid laws of light. Again, in the fifteenth and sixteenth centuries they resolutely grappled with the difficulty by composing the scenes to be represented in proper perspective, placing the personages and objects to be painted exactly as the things or people would themselves appear in the same situation. So we see in the ceilings of that epoch people who show hardly more than the sole of the foot, and others in which the knees hide the breast. Such boldness resulted in a great success. It is obvious, however, that if in such a method of decoration the horizon be supposed to be placed at a height of 2 yards from the ground, there would be only one point of sight, and that 2 yards above the floor of the room for the whole horizontal surface. Now so soon as the spectator shall move from this point of sight the perspective of the whole decoration will become false; all the vanishing lines begin to dance, and to give a feeling of seasickness to people who are accustomed to trust to the perspective power of the eyes. This system, however, can give good reason for its existence, since it had its origin, at least, in a reasoned out principle. It possesses a disadvantage, for it condemns the whole scheme of decoration of a room to appear true to one person alone—he who happens to occupy the proper point of view.

Ninth-Century Churches in Rome.

In the revival of Italian architecture from the Carolingian period, best exemplified at Rome by S. Maria in Cosmedin, S. Prassede, S. Maria in Dominica, SS. Nereo ed Achilleo, SS. Quattro Coronati, and in the towers of S. Vilestro, S. Maria Nova, S. Cecilia, S. Michele in Sassi (the last said to have been founded by Leo IV. especially for funeral Masses for the souls of those who fell in the defence against the Saracens, its beautiful tower and cornices the sole portion now left of the ninth-century building)—in this new style we see the tendency to admit more varied and fantastic ornament: terra-cotta cornices and corbels, inlaid work of coloured marble or earthenware on the dusky surfaces of those quadrate towers; small arcades with marble colonnettes, low porticoes or porches with heavy columns, mosaic friezes, and profuse decoration in the same art on the interior walls. Instead of the Classic capital a barbaric variation, sometimes in form a simple cube, takes its place at the summit of the shaft; and instead of the wooden roofing, with horizontal coffers or slanting beams, stone vaulting begins to be carried over the subordinate, though not yet over the principal compartments, as in chapels at S. Prassede and S. Benedetto in Piscinula, and in the aisles of the SS. Quattro. The campanili, divided into storeys of arcade-windows, with terra-cotta string-courses between, continued to multiply in Rome from the eighth to the thirteenth century, and are now indeed the sole structures, besides the picturesquely ruinous walls of the Leonine city, that remind us of Mediæval Christianity at this centre—at least, in the view of the city from high places. Such features as distinguish the public works of this period announce, indeed, a departure from the simpler type of the primitive basilica; but we may hail the innovation as proof, at all events, of life and progress, of art's correspondence with the age's impulse and feeling.

A Town Hall which has just been erected for the burgh of Prestonpans at a cost of 1,500*l.* was opened on the 9th inst. It provides accommodation for 450 persons, and was designed by Mr. Peter Whitecross, architect, Prestonpans.

NOTES AND COMMENTS.

IMAGINARY grievances are often the hardest to bear. Welshmen believe they are deprived of the dignity which is their due because the red dragon of Wales does not appear in the shield on one side of the coinage; it is also absent from flags and standards in which the royal arms are introduced. It was one of the subjects brought before the Eisteddfod at Newport. Principal RHYS, of Jesus College, Oxford, the President, maintained that Wales had as much right to be heralddically represented as England, Scotland or Ireland, but while Wales was deprived of all share, England held two quarters of the shield. The Welsh people, he said, had a sincere desire for the prosperity of the British Empire, but they would be more disposed to be brotherly towards their fellow subjects if they were treated with justice and regard for their feelings. One of the conclusions arrived at by the assembly was to move their representatives in Parliament and elsewhere to exert themselves to obtain a quarter of the shield for Wales. The Welsh do not appear to have given much attention to arms, and an expert in heraldry seems to have had no place in the organisation of society, but that is no reason to compel them to withhold a just claim, and the Welsh people form too important a part of the community to be unrecognised in any coat-of-arms which is a presentment of the constituents of this country.

A NEW use for the vapour of iodine has been found by Professor BRUYLANTS of Louvain. By its aid alterations in manuscripts can be detected. It appears that when a sheet of paper which has been sized and finished is moistened and then exposed, after thorough drying, to the action of vapour of iodine, the portion which has been moistened assumes a violet tint, while the remaining portion of the surface appears a brownish yellow. This principle may be used to produce a sympathetic writing, since if we write with water upon the surface of paper treated with ordinary size, the writing will appear in a violet colour when the dry paper is exposed to the vapour of iodine. The pale violet upon a yellow ground becomes a deep blue on a pale blue surface, when the paper is again moistened, and the characters disappear altogether under the action of sulphurous acid. When a manuscript is suspected of having been fraudulently retouched or altered, the use of the vapour of iodine will often serve to reveal the nature and extent of the alterations. Those portions which have been rubbed will become brownish in tint, and, when a rubbed surface is moistened after exposure to the iodine, it takes a blue colour, varying in intensity according to the duration of the exposure. The outline of the rubbed portions remains perfectly distinct after drying, being paler in tint than the rest of the surface. This action is evidently due to the removal of a portion of the starch contained in the size. These reactions also appear upon paper which has been entirely moistened and dried, as in the case of a letter copied in a press, but the indications are somewhat less distinct. The process will also reveal the existence of pencil marks erased by rubbing. Apart from any traces of plumbago which may have remained, the path of the pencil-point disturbs the surface of the paper, as would any blunt instrument, and, even when the rubbing has been so carefully performed that it has not removed any portion of the surface of the paper, the marks are made entirely legible when exposed to the iodine vapour. The clearness of all these reactions depends upon the character of the paper, and that which contains the smallest quantity of sizing material will naturally give the least brilliant effects; but in every case the changes above described will appear to a greater or less degree, and the use of the reagent in skilful hands should give material aid in clearing up disputed questions of this nature.

AN unusual exercise of authority by the Académie des Beaux-Arts has given rise to much discussion among French artists. In the competition for the Prix de Rome in the section of sculpture, the coveted award was found to be in favour of the model prepared by M. BOUCHER, who had studied under the three great sculptors, MM. FALGUIÈRE, CHAPU and MERCIER. Contrary to custom, the decision

which was arrived at by the members who are sculptors was set aside by the Académie des Beaux-Arts acting as the supreme judge. The Grand Prix was given to M. SÉGOFFIN, a pupil of MM. CAVELIER and BARRIAS, and the two other prizes to M. MAGROU and to M. VERMARE. It will be observed that the artist who was placed first by the jury is not considered worthy of an inferior prize by the Academy. So remarkable a difference among experts is deserving of more official explanation than is as yet forthcoming.

ILLUSTRATIONS.

CATHEDRAL SERIES.—CANTERBURY: TOMB OF THE BLACK PRINCE

PRINCE EDWARD must have been a man of remarkable precision, for the instructions he left for his monument are as detailed as if he were a sculptor and decorator. The greater part of his life was spent in the tented field, for he held a command at Cressy when he was barely sixteen. If all the amateurs of the fourteenth century were equally acquainted with details, it is no wonder the arts flourished. The BLACK PRINCE died at Canterbury and might be supposed to be well acquainted with the cathedral. But it is remarkable, that in his will he supposed that the body of St. THOMAS A BECKET was still lying in the undercroft, and his desire was for his tomb to be placed beside the martyr's. The spirit of the will was observed, and consequently the Prince's tomb was set up as near as possible to the famous shrine. One advantage was gained, for as the tomb is in one of the bays of Trinity Chapel the architecture becomes a setting for it, and its effect is enhanced to an extent that would be impossible if it stood in the centre of a chapel. The effigy in plate armour covered by a jupon and chain mail gorget is an excellent piece of work, and it is surprising that JOHN FLAXMAN did not refer to it when treating of English Mediæval sculpture. His connection with Cressy and Poitiers is enough to establish the Prince's reputation as a hero and a mirror of knighthood, but we cannot forget that, like ACHILLES, he could become inhuman. The massacre of Limoges a few years before his death reveals that he could give way to unmeasured cruelty. "There was not that day," says FROISSART, "a man in Limoges with a heart so hardened or so little sense of religion as not to bewail the unfortunate scene before his eyes. Upwards of three thousand men, women and children were slaughtered. God have mercy on their souls, for they were veritable martyrs!" The slaughter would have been greater if it were not for an incident which was recorded by MONTAIGNE. Amidst the general panic three French gentlemen were observed by the Prince to be attempting to resist his army. "Then it was," says MONTAIGNE, "that the consideration of and respect unto so remarkable a virtue first stopped the torrent of his fury, and that his clemency, beginning in the preservation of these three cavaliers, was afterwards extended to all the remaining inhabitants of the city."

LEAVES FROM SKETCH BOOK.

THE sketches by Mr. RAILTON which we give are all of English subjects, and suggest the character of the impressions which buildings make on his mind. Although quickly executed in order, as it were, that "the Cynthia of the minute" may not escape the artist's grasp, they contain sufficient materials to enable more elaborate drawings to be made from them, whether by the artist who had made them, or another who could not supplement them by recollection.

THE NATIONAL GALLERY OF BRITISH ART, MILLBANK, S.W.: INTERIOR OF GALLERY (THE GIFT OF MR. HENRY TATE).

THE gallery which is the subject of the plate contains some of the late Sir JOHN MILLAIS's pictures, *The North West Passage*, *Ophelia*, &c., as well as other modern pictures of lesser value.

ALL HALLOWS CHURCH, LOMBARD STREET: GENERAL VIEW.

THE interior of All Hallows, by the quantity of carving, suggests the church of a wealthy parish, but it has been submitted to severe alterations since WREN's time.

CATHEDRAL SERIES, No. 65.—CANTERBURY: TOMB OF EDWARD THE BLACK PRINCE.

HERTFORD HOUSE AND THE WALLACE COLLECTION.

THE following evidence was given before the special committee on the disposal of the Wallace collection by Sir John Taylor and Mr. A. Waterhouse, R.A.

Evidence of Sir John Taylor.

Chairman: You are the senior first-class surveyor in the Office of Works, I believe?—Yes.

Have you had an opportunity of examining Hertford House?—Yes, a general examination, but not one in detail.

Up to the present time that house has been used for residential purposes; but can you give us any idea as to its fitness for the purpose of a public exhibition of the collections it contains?—The new portions of the building were, I believe, constructed for the express purpose of an exhibition; but in regard to the older portions of the building I have no accurate details to offer.

Sir F. Mowatt: Can you speak positively in regard to the modern portions of the building?—I was told that the construction was fireproof.

Chairman: With regard to the approaches and to the means of ingress and egress, do you think the building is a convenient one for the purposes of an exhibition?—The means of ingress and egress as they stand now are not suitable for a place used as an exhibition. The place was really not constructed for an exhibition though of late it has been used for that purpose as well as being used as a private residence. If the original entrances to the building were all thrown open, I imagine there would be sufficient means of egress for exhibition purposes; there would, however, be no second entrance to the building, though I understand that hitherto when visitors were admitted they went in at Spanish Place.

Mr. Mitford: Would not the ingress in Manchester Square suffice, providing there was no meeting of the tides of people at any one point?—Yes, I think so.

Chairman: Can you give the committee any idea of the amount of space available at Hertford House?—Yes, I have prepared a rough statement of that. Taking the rooms occupied by the exhibits on the first floor and on the ground floor together, I find the floor area to be about 18,000 feet; and the wall space at present occupied in those rooms I estimate as about 34,000 superficial feet.

Sir F. Mowatt: Does that include the residential rooms?—Yes, those used for the purposes of exhibition. That is the net total wall space at present in use at Hertford House for exhibition of works of art. The lineal extent of the walls is about 1,950 feet. For the purposes of comparison I had the corresponding measurements taken of the extensions of the National Gallery which were carried out by Mr. Barry in 1878 and by myself in 1887. The area of the floor space at Hertford House, taking the first and the ground floors together, comes to 18,000 feet, while the floor area of the two extensions of the National Gallery which I have named amounts to 24,500 feet, and their lineal measurements amounted to about 2,000 feet, as against the 1,950 in Hertford House.

Chairman: Are those portions of the National Gallery which you have taken for the purposes of comparison the portions marked grey and blue on this plan?—Yes.

Mr. Armstrong: Will you give us the area of the first extension of the National Gallery?—The floor space of the first was 15,780 feet and of the second 8,730 feet. The line of the wall in the first or the grey extension is 1,287 feet, and in the second or the blue it is 734 feet.

Chairman: Coming back to Hertford House for a moment, have you at all considered whether the house could be so altered as to appropriate certain rooms which are now used for other purposes to the purpose of exhibiting the collection?—Yes, I have ascertained that a very considerable addition might be made to the exhibition space in Hertford House.

Can you in general terms give the committee the opinions you have arrived at as to the reappropriation of the space at present occupied and the possible erection of new buildings to receive a part of the collection?—The alterations would principally be made in the stable portion of the building, and in the portion of the residence which has been used for offices. Some of those offices are on the ground floor and some in the basement. A large portion of the building, the stables and the coachhouse, which is not now used, could be altered and utilised for exhibition purposes.

Sir F. Mowatt: Would that bring us into contact with other buildings?—No, because a street bounds the stable yard.

Chairman: If those stables and offices were converted into galleries, how would they be lit?—By means of side lights looking into the streets and into the courtyard.

Do you think both the western and the northern galleries could be well lit by side lights only?—Yes.

Passing to the eastern side of the block, still on the ground floor, have you anything to say about the room now used as a smoking saloon?—I think that was intended as a saloon for sculpture, and that there are some pieces there now.

Would that part also be available for an exhibition gallery?—Yes.

Does anything occur to you in regard to the ground floor of the house itself?—I think some changes might be made to increase the accommodation; that is, on the western side where there are now the rooms occupied by the butler and the housekeeper.

Could they be converted into galleries with side lights?—Yes, and they might have screens similar to those now used in the National Portrait Gallery.

Would there be any possibility of utilising a part of the space now occupied by the garden for the erection of new galleries?—Subject to everything being so arranged as not to interfere with the side lights of other galleries.

Would there be any room for a central gallery across the courtyard without robbing the eastern and western galleries of too much of their light?—I think the idea of a central gallery had better be left out.

Mr. de Rothschild: Do you think the means of egress on the ground floor could be materially improved; there is a small door there where you can get out?—That door is on the east side, and it takes you into the street.

Yes, but could not the means of egress be materially improved?—There would be no difficulty in getting egress either side, whichever you like; there is no practical difficulty about that. If that were done it would leave the principal entrance practically free as an entrance.

Chairman: Have you any observations to offer in regard to the space available on the first floor?—I have not fully considered what could be done by way of increasing the accommodation. I have made my examination principally with a view to seeing what exists and whether the building could be adapted.

Have you considered the question of access to the first floor?—I have no doubt whatever that any improvements required in that way could easily be carried out.

Does it occur to you that it would be possible to give, on the first floor as well as on the ground floor, some such improved means of egress as Mr. de Rothschild suggested just now?—There is the staircase in the eastern picture gallery which gives access to the ground floor immediately below.

Could the same sort of staircase communication be provided on the western side?—Yes, there is no doubt about that.

I see on the western side of the plan rooms marked "Lady Wallace's dressing-room," "Lady Wallace's bath-room," "Sir Richard Wallace's dressing-room," are those rooms occupied by works of art now?—Yes, I have taken them into account. They are partially occupied by works of art and I have included them in the figures I have given.

Sir F. Mowatt: Have you on your estimate of wall space included the walls that are now occupied by cabinets?—Yes, to a certain extent.

Sir E. J. Poynter: Can you give us the area of the large gallery?—I think it is 120 feet long by about 35 feet wide.

Chairman: What is there above the first floor?—I have not been through the upper portions of the house, but I think there are only bedrooms above the first floor.

Have you any suggestion to make in regard to using any portion of the upper part of the house for exhibition purposes?—I do not think it would be fit for such purposes.

Sir F. Mowatt: Do you mean they would not be fit for pictures?—Yes, I think the rooms would be too low.

But would they be too low for such exhibits as cases containing snuff-boxes and miniatures?—Not too low if the light were sufficient.

Mr. Waterhouse: I think the rooms are about 10 feet high?—That is not very high for a room that may be crowded, but of course it might be used.

Mr. Mitford: Do not you think we want some rooms for the servants and the staff?—I do not think servants ought to be lodged in such a building; I think it would be better not to have them living in the house. There are the lodges.

Sir E. J. Poynter: Do you think it would be possible to increase the skylight area of the galleries?—I have not considered that point, but I do not think it would be possible to increase the skylight area of the rooms now so lighted.

Sir F. Mowatt: But a gallery could be carried across the present courtyard?—Yes.

Could a connecting gallery between the present eastern and western galleries be carried across the courtyard and lighted from above by a skylight?—Yes, but I think it would be better to leave that gallery out.

Chairman: If you constructed a gallery across the courtyard that would darken the rooms now used as a billiard-room and as a dining-room, would it not?—To a certain extent; it would all depend upon the height.

Mr. de Rothschild: You can get more top-lighted galleries for pictures by removing the armoury, can you not?—Yes.

Sir E. J. Poynter: Do you know the area now lighted by skylights?—Judging by the plan I should say the area would be 7,164 square feet.

And that is all the available top-lighted space unless you build a gallery across the courtyard on the ground floor?—Yes.

Chairman: Can you give us an approximate estimate of the cost of acquiring Hertford House for the nation?—Yes. I had occasion to make a valuation and it came out very nearly to the same amounts as those asked by the leaseholder and the freeholder for their interests. The leasehold interest was valued at 35,000*l.* and the freehold at 30,000*l.*, and those figures I consider quite reasonable. I believe some change has since been made in the price asked for the freehold, but it has not come before me.

To that total sum, whatever it may happen to be, would have to be added the cost of the alterations to the rooms if any were made?—Yes.

I suppose it would be impossible for you to give us anything like a close estimate of the cost of those alterations, but have you in your mind the kind of sum which would cover that cost?—That could only be accurately ascertained when the proposals as to alterations are put into a definite shape, but I think 10,000*l.* to 15,000*l.* would go a long way towards it.

Mr. Mitford: That would not include the cost of an additional gallery across the courtyard?—No.

Mr. Waterhouse: Would that amount of 15,000*l.* include the cost of the conversion into galleries for exhibition purposes of the rooms on the ground and first floors which are not now so used?—Yes; the stables, for instance.

Mr. Armstrong: Is that supposing the alterations to be carried out on the same scale of dignity as that which obtains in the rest of the building?—I am assuming that nothing very elaborate would be done on the lower floors. I do not think that is required.

It is not proposed to make the new exhibition rooms differ from the old, is it?—Some of the old are decorated in a very expensive style; I have not estimated for marbles and things of that kind.

Sir F. Mowatt: Would you say that the large picture gallery was in any way exceptionally magnificent?—The large picture gallery is arranged for top lighting, and you cannot get top lighting on the ground floor, to which my estimate has reference. I have only taken into consideration the cost of preparing the rooms for exhibition purposes, but I have not estimated for costly materials.

Mr. Armstrong: Can you give us any idea of what it would cost if the new rooms were treated in the same way as the old ones, so as to make the whole thing harmonious?—I could make such an estimate if required.

Mr. Waterhouse: Is it not the fact that the new galleries built by Sir Richard Wallace are treated in a very much simpler way than those in the older portions of the house?—Yes.

Mr. Armstrong: Do you think the house could be so modified as to afford absolutely free admission to the public without any inconvenience, so that any number of people could come and circulate as they please?—Yes, the building could be made to admit people as freely as the National Gallery does now.

Mr. Waterhouse: Can you tell us the height of the rooms on the ground floor which it would be possible to convert into galleries?—To the best of my recollection they are about 18 feet high.

Can you tell us what would be the extra accommodation in floor space which would be obtained if we turned those portions of the ground and first floors into exhibition galleries which are not so used at present?—I should say something like 7,000 feet.

Then we should get altogether something like 32,000 feet of exhibition space as compared with the 15,780 feet of space available behind the National Gallery?—Yes, if you add the portion which I built to that erected by Mr. Barry; but you must remember that in dealing with the space behind the National Gallery, I have taken one floor only, whereas at Hertford House I have taken two floors.

On the site behind the National Gallery could we have two storeys of exhibition space—is there sufficient light for that?—Yes, if the building is a detached one.

And with as good a light as we could get from Manchester Street?—I am not prepared to say that the light would be so good, because the buildings of the National Gallery are of considerable height, and if another building were added there would be a certain amount of shadow thrown over the new buildings by the existing ones.

Mr. de Rothschild: In your estimate of the probable cost of the alterations, have you considered the necessity for improving the skylights over the long gallery, the two other galleries and over the staircase?—No.

That would be a material improvement, would it not; because at present they are very unsatisfactory?—My examination of the building has not been sufficiently detailed to take in all the improvements which might be effected.

Sir E. J. Poynter: If the public were admitted to Hertford House as freely as they are now to the National Gallery, how would it be necessary to rearrange the furniture?—I think the furniture could be rearranged in the additional space which we

should get in the extensions I have suggested; we could then take away from the gangways a considerable number of cases which are now in the direct line of route round the rooms.

Would it be possible to keep any of the rooms as they are at present in regard to their furniture?—I think some of the rooms are too crowded with exhibits at present, they would certainly require to be rearranged.

Notably the famous boudoir of Lady Wallace?—Yes, certainly.

What would be the additional area gained by making a gallery across the courtyard?—About 1,500 feet roughly.

Chairman: With regard to what you said about there being sufficient room for the number of visitors who might be expected, I suppose what you had in your mind was an ordinary number and not the number who might be attracted when the collection was first thrown open, and which might be an exceptional crowd?—I think there would have to be some restriction put upon the numbers admitted at first; I have no doubt the public will at first be much interested in seeing this collection, and there will be a rush.

But if the proper precautions were taken there would probably be sufficient space for the ordinary number of visitors who might be expected to come, would there not?—Yes.

Mr. Mitford: Have you formed any sort of idea as to what length of time it would take to prepare Hertford House and get it ready for the exhibition of the works of art that it now contains?—I should think it would take from six to eight months to complete the structural portion of the work.

Chairman: Turning now to the National Gallery, with reference to the portion coloured pink on this plan, I understand that represents the contemplated extension which was designed to provide for the normal expansion of the National Gallery?—Yes. That extension has been under consideration for years, and from time to time we have been in communication with the War Department with a view to getting a portion of the barrack yard for the purpose of carrying it out.

Would such an extension, assuming that the National Gallery did not require it for its own purposes, afford sufficient room for housing the Wallace collection?—I think it would be scarcely sufficient. The area which has been given to the National Gallery extensions has been of one floor only, but two floors are possible for exhibition purposes.

At any rate, may we take it that if the Hertford House collections were lodged in the pink extension they would take up the whole of it, and that nothing would be left over for what might be called the normal expansion of the National Gallery?—That would be so.

Supposing the Hertford House collections were brought to Trafalgar Square, has it ever occurred to you whether it would be possible to obtain room for them by further extensions involving the appropriation of land lying to the west of the present National Gallery buildings?—Any extension in that direction would involve the purchase of a site. I have taken out the area of the block occupied by Watherston's and Hampton's and extending back to the next street as shown on this plan.

You mean the block bounded on the south by Pall Mall East, on the west by Hedge Lane, on the north by a narrow street running towards St. Martin's Lane, and on the east by the National Gallery buildings and the barracks?—Yes, and the area of that is about 33,600 feet. If we required that site we should have to take compulsory powers in order to get it.

That site is now occupied by business premises the goodwill of which is, I presume, of very great value?—Yes.

Are you able to form any conjecture as to the terms upon which that block could be acquired?—I think it would cost at least 300,000*l.* or 350,000*l.*

And to that would have to be added the cost of any new buildings that were put up?—Yes, and a building with such a street frontage as that would require suitable architecture.

Mr. Mitford: What would be the cost of such a building as you have in your mind?—I should say that a building of sufficient size, put up on such a site as that, would cost not less than about 125,000*l.*, perhaps more.

Chairman: With reference to what you said just now as to the time required for carrying out the alterations at Hertford House, I presume it would take a great deal longer to appropriate the present occupants of the Hampton block and to put new buildings upon it?—It would certainly take not less than five or six years.

That is evidently a very expensive block. Is there any other site in the neighbourhood of the existing galleries the acquisition of which might be entertained by the committee? Here is a block bounded on the north by Spur Street, and running south and west of Leicester Square?—I think you would require also the block to the eastward—that is, between St. Martin's Street and St. Martin's Baths; I think both those blocks would have to be taken in order to obtain the requisite amount of accommodation.

That would take in the whole south front of Leicester Square?—Yes.

Can you give us any idea as to the difficulty or otherwise of acquiring that block?—I think there would be the same difficulty in acquiring that block as there would be in acquiring the Hampton block; there are the usual trade and professional interests. The block between Spur Street and Blue Cross Street contains 26,400 superficial feet, and the block to the eastward contains 19,800 feet, giving a total of 46,200 feet; and the cost of acquiring those two blocks would be about 250,000*l.* or 300,000*l.*—land is not quite so expensive there.

What would be the cost of building upon that block?—Something about 150,000*l.*

Have you anything to say in regard to that site in respect to convenience of access?—It would be convenient of access from the Leicester Square side, but on the other side I think it would be rather hampered.

Do you think, considering that we have to provide for a building and collection of great national interest and importance, that the Leicester Square site is one that you would naturally choose if you had a free choice?—No, and for various reasons, the principal one being that it is surrounded on three sides by other properties, some quite close to it, liable to fire at any time.

Would you say that those properties could hardly be described as of very high class?—That is so; they are a very secondary class of property.

Is there any other central site that occurs to you, supposing we are seeking for a new site?—I have not one in my mind at the present moment.

Mr. Armstrong: If the proposed addition to the National Gallery were made, you could not use more than one floor without abandoning the whole scheme upon which that building has been arranged. The lower floor of that part marked pink could not be made available for exhibition purposes?—The lower floor and other portions of the gallery recently added are not used for exhibition purposes, they are only used as repairing rooms and for purposes of a similar nature. I think an arrangement might be made by which some of the rooms might be used as side-lighted rooms. But the lighting for the lower rooms would be by no means perfect.

The accommodation at the National Gallery is too small now, is it not, and if you used up the space outside you would hamper the future extension of the National Gallery for its own purposes?—Yes.

Do you think, for a dignified public building, there is any advantage in taking a site which is not occupied by other dignified buildings?—Subject to the surroundings being made to correspond with the new building to a certain extent, there would be no objection to such a site; but if the old buildings are to be left as they are, I think it would be most inappropriate.

Is it not certain that Whitcombe Street will be widened into an important street?—I have not had that before me.

The Leicester Square site comprises 46,240 feet?—Yes, but you could not utilise the whole of it because the new building, if large, would have to be set back within the line of the present frontages. The site is larger than the buildings required, but I do not think it would be much too large when the buildings were set back.

Then you do not see any advantage in that site, not even in its proximity to the other national collections?—It is desirable to have the collections as near together as possible, but I do not think that is a good site for such a building as that now in contemplation.

Mr. Waterhouse: Can you state the whole area of Hertford House, with a view to comparing it with the Leicester Square site?—The area upon which Hertford House stands contains about 22,000 feet; the Leicester Square site is more than double that.

Comparing Hertford House and the site behind the National Gallery, which do you consider is the better for light on the ground floor?—Hertford House, distinctly.

Which do you consider is the safer in regard to fire?—With their present surroundings, Hertford House.

Sir E. J. Poynter: With reference to what has been called the Hampton block, would it not be desirable in any case to purchase at least a portion of that on account of its contiguity to the National Gallery and the danger of fire?—Unquestionably. The further the National Gallery is from such premises as those the better for the Gallery.

Is it not likely that that will be done?—I have doubts about whether it is likely to be done; it would be a very expensive operation. Nothing short of the formation of a new street would attain that object.

In reference to the acquisition of the Hampton block, would it be necessary to take the whole of that for the Wallace collection?—would not half the block do?—Hertford House now stands upon 22,000 feet and the Hampton block is 33,600 feet; but any new building put upon the latter would have to be set back considerably on the western side, and therefore a great deal of the site would be lost.

Then you would, under such arrangement, use the whole of that site for the Wallace collection and leave this pink portion for the extension of the National Gallery?—Yes.

Chairman: What would be the cost of the pink extension if carried out for the National Gallery?—From 75,000*l.* to 100,000*l.*, I think.

Suppose the pink extension were carried out and used for the purposes of the Wallace collection, what means of access would there be to that extension other than through the National Gallery?—None whatever.

Then it would be virtually impossible to obtain access to the collection except by passing through the National Gallery?—Absolutely impossible, unless the War Office would give up some land for the purpose, which we are told cannot be done at present.

Supposing, for the sake of argument, that the War Office did give up the remainder of its barrack accommodation, do you think it would then be possible to get a suitable and dignified approach to the new Wallace Gallery from the Orange Street side?—No.

Mr. Mitford: Supposing that pink site is given up to housing the Wallace collection, how do you propose to provide for the extension of the National Gallery?—I do not see any reasonable way of doing that; it would create a difficulty all round.

Has not that pink site always been regarded as sacred to the future extensions of the National Gallery?—Yes, and the Trustees have always pressed that upon us.

Chairman: But, putting that on one side, you do not see how to provide there a suitable and appropriate building for the Wallace collection?—No, unless the Government go to the expense of purchasing sufficient property to provide a new street.

With regard to what is known as the War Office tunnel under the National Gallery, you do not think that would be a very appropriate entrance to the Wallace collection, do you?—I think it would be most inappropriate.

Evidence of Mr. A. Waterhouse, R.A., a Member of the Committee.

Chairman: We understand that you have lately visited the Hertford House galleries?—Yes, I was there yesterday.

Will you tell the committee what opinion you have formed of the manner in which the collections are accommodated?—I thought the collections were well exhibited on the whole, but the light in the top-lighted galleries might be improved, certainly in the large gallery, by the removal of the old sun-lights. The light in the old portion of the house is certainly not entirely what it ought to be, and that is especially the case with the rooms looking into the internal court. If the collection were kept where it is, I do not see any difficulty in improving the light.

Do you agree with what Mr. Taylor has said as to the possibility of considerably adding to the amount of space available for exhibiting the collections?—Yes; I think the space might be increased largely; to the extent of 7,000 feet of floor area.

You have heard what Mr. Taylor said as to the improvement of the means of ingress and egress; do you agree with him?—Yes, I think subsidiary doors might be arranged which would provide convenient modes of egress. The approach from Manchester Square would be the most convenient means of entrance.

Mr. Mitford: Side doors do you mean, in each of the other three sides of the building?—I alluded especially to the two sides of the building, but there might be a third door at the back in George Street. I may say that before I revisited Hertford House yesterday I was not very much in favour of the retention of the collection there; but when I saw all the care that had been lavished upon it in the decoration of the rooms and in the matchless chimney-pieces, which form an integral part of the rooms and a most valuable portion of the bequest, it seemed to me that there was very good reason for retaining the collection where it now is. If the bequest were taken away from its present surroundings it could never be shown to such advantage; in fact, we should lose the association of the giver with the bequest, and the bequest is alive with such association now. Re-erected in another place, the staircase, for instance, would never look so appropriate as it does in its present position. The same with the fireplaces and the candelabra.

May we take it that you are disposed to regard the collection as something more than a mere aggregation of pictures and works of art? You look upon it as a collection accumulated by a man of great taste and discretion, with an air of inspiration about it that might not survive if it were removed to some other building?—I think the interest of the collection would be sadly marred by its removal from its present quarters. Then, again, there is the question of fire, which seems to be a very important one. The building has wide streets on three sides and a square on the other, and although not constructed on the most approved fireproof principles, I think it is much safer than any building constructed at the back of the National Gallery would be with its present neighbours on the north and west. I should like to refer to the subject which I brought to

the notice of Mr. Taylor, namely, the lighting of the rooms on the ground floor. It seems to me, and he confessed the same thing, that the additions to the National Gallery, which were planned and carried out by Mr. Barry, afford no exhibition space on the ground floor; but at Hertford House it certainly would be otherwise, because the light there is very good. We have wide streets all round, and a large internal courtyard.

Mr. Armstrong: Do you think the courtyard could be covered in without any great detriment to the other parts of the house?—No; I think that would be sure to affect injuriously the light of the rooms on the ground floor looking into the courtyard.

Chairman: Would you say that in regard to a proposal to cover in part of the courtyard?—A small gallery running through the centre from east to west, if kept low, would not perhaps affect the light.

But a gallery running along the sides?—That would affect the rooms which are the darkest already—they would not bear anything of that sort.

Sir F. Mowatt: Do you think, with the additional gallery you have suggested, that Hertford House would afford sufficient accommodation for adequately exhibiting the whole of the collection?—I think it could so be made capable of affording suitable accommodation.

Mr. Mitford: Do not you attach importance to the fact that whereas it would take from five to six years to purchase and make ready a new site, Hertford House could be got ready and handed over to the trustees in from six to eight months?—Yes, I think it most important to give the public access to such a collection at as early a period as possible, and that object could only be attained by leaving the collection where it is.

SOMERSETSHIRE ARCHÆOLOGICAL SOCIETY.

THE annual meeting of the Somersetshire Archæological and Natural History Society was held at Bridgwater on Wednesday, Thursday and Friday in last week. According to the report in the *Somerset County Gazette*, which we have employed, it was twenty years ago the Society last visited Bridgwater, and therefore the district was new to the majority of the members, while those few who took part in the gatherings of 1877 were delighted to renew their associations. As in former years a museum of objects of archæological interest and of specimens of natural history, particularly from the district visited, was formed, and the articles were arranged in the committee-room at the town hall under the direction of Mr. Bidgood. They formed a very interesting collection, and attracted a good deal of attention.

The annual general meeting was held in the town hall, which was decorated with a large series of rubbings of ecclesiastical brasses, principally representing the East of England. These were kindly lent by Mr. H. Corder, of Bridgwater, and were of a representative character.

The Rev. F. W. Weaver, M.A., one of the hon. secs., read the annual report of the council of the Society as follows:—Your committee beg to present their forty-ninth annual report. During the year 37 new names have been added to your list of members. On the other hand, the loss by deaths and resignations has been 17, leaving a net gain of 20 members. The number is 589, as against 577 at the date of our last report. A county society, numbering close upon 600 members, can undoubtedly claim a leading position; but there are still many names which your committee would desire to see enrolled among their members, and they have to express a hope of a still further increase during the ensuing year. The debit balance on the Society's general account has during the year been reduced from 20*l.* 0*s.* 8*d.* to 9*l.* 6*s.* 9*d.* The cost of the volume of proceedings was 77*l.* 6*s.* 5*d.*, as against 108*l.* 12*s.* 6*d.* last year, or 192*l.* 4*s.* 5*d.* in the previous year. The debit balance of last report on the castle restoration fund has now been reduced to 44*l.* 11*s.* 9*d.* Your committee regret to state that the Castle House still remains void. During the year ending December 31, 1896, the number of visitors to the Museum was 4,610, as against 4,964 in 1895. The index to Colinson's "History" is making satisfactory progress. Upwards of 100 pages have already been printed. The committee have pleasure in announcing that Mr. F. T. Elworthy has prepared and kindly placed at their disposal a full and complete index to volumes xxi.-xl. of the Society's proceedings, carrying to that date the index to the first twenty volumes issued some years ago. This is now in the press and will be issued to subscribers at 5*s.* per copy. The "Bibliography of the County," prepared some years since by Mr. E. M. Green, F.S.A., is also in the press, and will be issued to subscribers at 2*l.* 12*s.* 6*d.* per copy. Subscribers to all or any of these publications are earnestly solicited. A deed has been prepared for the purpose of formally carrying out the appointment of new trustees made at the last annual meeting, and is now in course of signature. The additions to the library during the current year have been numerous and important. At the suggestion and on the appli-

cation of your hon. secretary, Rev. F. W. Weaver, the deputy-keeper of the records has forwarded twenty-one volumes of the publications of the Record Office in exchange for a complete set of the Society's proceedings. Mr. John Batten, F.S.A., past president, and one of your trustees, a staunch supporter of your Society, has presented a complete set of annual reports of the deputy-keeper of the Public Record Office, the *Journal of the Royal Agricultural Society*, 1839 to 1895, and other volumes. About fifty monographs on natural history and antiquarian subjects have been received from the Royal University of Upsala in exchange for a number of volumes of the Society's proceedings. Numerous other volumes have been received by exchange, purchase or donation. Your Society has been fortunate during the past year in losing few members by death, but amongst the number they deeply regret to record that of Mr. Edmund Chisholm-Batten, for a very long series of years one of the most active supporters and a constant attendant at the meetings of your committee, where he frequently occupied the chair. A resolution of sympathy has been passed and communicated to the family. In their last report your committee suggested that the annual meeting in 1898, when your Society will have entered upon the fiftieth year of its existence, should be held at Taunton, its headquarters and birthplace, and that a strong and well-organised effort should be made on that occasion to provide a fund for the repair and preservation, not restoration, of the castle. The numerous festivities which have marked the current year have rendered it undesirable, well nigh impossible, that any steps should be taken in the direction indicated. Now it is time that the matter should be taken seriously into consideration, and your committee trust that every member will do his or her best to render the archæological week of 1898 a complete success.

The presidential address was delivered by Mr. E. J. Stanley, M.P. He said it was the custom of the Society that he whom they honoured by electing President for the year should address a few observations to them on such points of the archæological or other questions of the district as he might think desirable to bring to their notice. He must thank them, after twenty years, for having invited him to become their President. On the first occasion he had to send an excuse to the Society, and he did it with great regret, although the circumstance which obliged him to be absent was one which he knew would give him great happiness, which had continued ever since. He had read as much as he had been able of the different opinions of different people regarding the antiquities of the neighbourhood, and he was sorry to find the opinion of one who said that they were not many in number and had been frequently described at great length. He did not think that was right, and he thought he could point out several features of special interest which were not included in their list of tours for the next three days. He believed they would find that the natural history department had not been very much considered by the Society, and there were several quarries near Quantock Lodge which were of an interesting character. He had the authority of so well-known a geologist as Sir Roderick Murchison for stating that the quarry of green stone, of which Quantock Lodge was built, was of very great interest. Most people who saw the house considered that it was built of green sandstone, but it was not so, for the stone used was a highly igneous rock which took a polish, and the party visiting Quantock Lodge on the next day would see a table of the polished stone. The late Rev. Mr. Lance, of Buckland St. Mary, had had some columns of the stone polished, with which he decorated his beautiful church, which was still being adorned and beautified. There was another large quarry near the Lodge, in which the stone alternated very largely, and it contained building stone and limestone, which when burnt produced lime as well as polished marble. From this quarry a large chimneypiece for Dunster Castle was carved for Mr. Luttrell. Another object of interest was a cave at Holwell, which had never been thoroughly explored. There was a little difficulty in the exploration, inasmuch as to make further progress one had to crawl upon the knees, and as the ground was rather wet people shrank from further explorations. Some day, however, it might be completed, and it was rather curious that in a limestone district like the Quantocks it should be the only cavern of which they had any knowledge. There were also in the district the remains of the workings of upper mines, as he knew to his cost, because after heavy rains the soil fell in and he had to send several cartloads of soil to fill up. In addition there were a number of marble quarries to which a certain interest attached. If they had time on the next day some might like to visit the quarry from which the stone of Quantock Lodge was obtained. Sir Roderick Murchison had expressed the opinion that it was igneous rock from very near the crater of a volcano, but he reassured those to whom he told that by saying that it was not likely that the volcano would break out again in the same place. There was one portion of their natural history in which he would like to destroy a fallacy. There was a general belief that, as on Exmoor, which had been a Royal forest from time

immemorial, so in the Quantocks red deer had been for centuries. These beautiful animals, however, were claimed to have been first turned out on the Quantocks by Mr. C. E. J. Esdaile's father, and this was confirmed by Lord Ebrington. Speaking of Admiral Blake's connection with Bridgwater, he said a large number of the Blake family from America and elsewhere often came to Plainsfield Farm to see a chimneypiece there, on which were carved the letters "E. B.," but the date 1688 showed they were placed there long after the admiral's death. What was the meaning of the initials would be an interesting question to solve. Then, again, in Over Stowey Church, in front of the communion table, there was the tombstone of "Humphrey Blake, clothier, of Bridgwater, died 1619," while they knew that Humphrey Blake, the admiral's father, lived to a later date. He had known the clergy a good deal worried by descendants of the Blake family for particulars as to the relations of the admiral. One, after getting a copy of the register, wrote to know if any of the family had been omitted, and the clergyman wrote back saying he had forgotten to mention one Edward Blake, who was put in the stocks. An interesting question which had come rather prominently before them of late years was the great part which ladies took in holding property in that neighbourhood. As to his own position, he had himself bought a few farms, but the great mass of the Quantock Lodge estate belonged to his wife. Then close by, at Brymore, they all remembered the fact of Miss Hailes leaving that property to Mr. Bouverie's grandfather, while the large estate of Fairfield descended to Sir Peregrine Acland's daughter. Further on there was Crowcombe Park, which belonged to the wife of Mr. Trollope, and next there was Mrs. Bisset, of Bagborough, and long might she continue to enjoy the beautiful property which she owned. A little further on was the Tetton property, which came to the Earl of Carnarvon's family by marriage with one of the Aclands, and which had previously come to the latter by marriage with the Dykes. Then there was the Portman property, which came to the Berkeley family by a marriage with the heiress of the Portmans. Pixton Park also came to Lord Carnarvon through marriage with an Acland. Further west they met with the extraordinary fact of the Dunster Castle estate having been sold only once since the Conquest. It was given to Lord de Mohun by William the Conqueror. One of the Lords de Mohun was known as Earl of Somerset, and his wife, who had great influence over him, got him to leave the property to the Archbishop of Canterbury and others, who were to do with it as Lady de Mohun desired. She desired them to make the property over to her, and then, retaining the use of it to herself for life, she sold it for a sum of money to Lady Elizabeth Luttrell, who had three daughters—the Duchess of York, the Countess of Salisbury and Lady Strange of Nocking. The Duchess of York and the Countess of Salisbury died without issue, and Lady Strange of Nocking carried on the line. On the sale of the property by Lady de Mohun legal proceedings were taken, and an almost unprecedented thing occurred, for the House of Commons petitioned the Crown that it should be tried at bar. This was probably obtained by the influence of the Duchess of York. The trial was ordered to take place at Ilchester, but there was no record of the result, although the property remained with Lady Elizabeth's son. He (Mr. Stanley) was directly descended from Lord and Lady Strange of Nocking, and it was rather interesting to find himself settled in Somerset for twenty-five years, and then after all to find himself to be a Somerset man. There were other properties held in the same way. Halswell, for instance, came to the present worthy owners through an heiress, while an interesting fact was that the first document he ever signed as a Somerset magistrate was one brought to him by Mrs. Farthing, who was churchwarden of Dodington.

The Mayor proposed a vote of thanks to Mr. Stanley for the very able and attractive address he had given them on that occasion. He was sure they must have listened to it with a vast amount of interest and pleasure. He (the Mayor) hoped time would enable them to visit the quarries alluded to by Mr. Stanley, for they were a very instructive and interesting feature of the neighbourhood.

The Right Hon. J. W. Mellor seconded. He said there was no one better qualified than Mr. Stanley to preside over them. He (Mr. Mellor) had known Mr. Stanley for many years, but that gentleman had never previously told him that he was of Somerset descent. He was very glad indeed to hear that Mr. Stanley was a Somerset man, as that would give additional interest in the proceedings.

The vote was adopted with acclamation.

The Chairman briefly acknowledged the compliment, and this closed the meeting.

St. Mary's Church, Bridgwater.

After luncheon the company proceeded to St. Mary's Church, where the diocesan architect, Mr. E. Buckle, gave an interesting description of the building. He said it was quite impossible to look at that church with any attention at all without feeling

what an important place Bridgwater was in the olden time. It was really a larger church than it gave one the impression of being, and he believed that it seated something like 1,300 people. It was not surprising that Bridgwater should require a church of that size now, but it was really surprising that as far back as they could go there appeared to have been a church there as large as the present one. There was nothing of Norman work left, but the foundations of the Early English building extended all the way around the north aisle, and at the end of the north transept they found again some Early English foundations. That appeared to make it plain that in the thirteenth century there was a cruciform church with aisles and nave of the same width as the existing ones. Mr. Buckle then pointed out how wide it was across the nave and aisles, and said that in the thirteenth century it would have been designated a remarkable church. In the time of King John there was no doubt there was an hospital of Augustinian canons in Bridgwater, and the church was the property of these canons, who served it by one or two of their own number, while a chaplain was appointed as well. The only serious additions to the size of the church made since the time of these canons appeared to be the filling out of the space between the transepts and the nave aisles, and additions at the east end. The two side chapels were probably added later, and the chancel carried at least one bay further east than it was at that time. Of that Early English church nothing remained but the foundations and the lower part of the wall. Mr. Buckle pointed out the early niches for monuments and also the very remarkable piece of thirteenth-century work in the north door, which, however, was not *in situ*. He described the tracery of the window over the door, and said the position of the outer walls and arcades had always been the same as now, and very little alteration at all had taken place in the general appearance of the church, except as regarded the removal of the cross arches from the centre and the raising of the nave. The windows were of all sorts of dates. They had a Geometrical window, Decorated windows and windows with reticulated tracery. In one aisle they found the internal arch of the old windows remaining, whilst the windows themselves had Perpendicular tracery inserted all through. The great change which had taken place in the church was the removal of the cross arches and the addition of the clerestory. The arches varied a great deal in width, and the capital of one dropped down quite a foot. Another remarkable fact was that the clerestory windows were not over the arches, but over the pillars—a curious and quite meaningless arrangement. The old rood-screen was now utilised as choir screens, and a remarkable fact was that in olden time there was in front of the rood-screen another screen some 6 or 8 feet forward. This was a Jacobean screen, which now formed the front of the Corporation pew, and the Mayor and Corporation seemed to have been provided with seats between the two screens. Altogether the church must have been wonderfully rich in carved work, because the whole of the front of the stall-work in the chancel was filled out with panels of ancient carved work. The pulpit was a pretty one of Perpendicular date, and formerly stood against one of the pillars further down the nave. Mr. Buckle spoke of the arrangement of the squint through the north porch, and said the purpose of these squints was generally supposed to be to provide for leper houses. Speaking of the furniture of the church, the most conspicuous thing was the picture presented to the church by Mr. Anne Poulet, who was christened Anne after Queen Anne, and was at one time member for Bridgwater. Beyond that fact no history of the picture was known, but it was generally ascribed to an Italian artist. There were at one time at least seven altars in the church, as had been discovered by Mr. Weaver. They were the High altar, Trinity altar, Our Lady's altar, St. George's altar, the rood altar, St. Catherine's altar and St. Audry's altar, and there appeared also to have been an altar to St. Erasmus. There was ample room for seven altars, and there might very well have been more. There were three chantries, St. George's, Our Lady's, and the Holy Trinity's, and there were seven guilds in connection with the church. All these things pointed to the great richness and importance of the town. The small arch leading into the tower showed that at the time it was built there was no clerestory. The tower was a massive building consisting almost solely of rubble stonework, without any freestone where it could be avoided. The tower, in contrast to the church, showed poverty, but it had a really remarkable spire, being a great deal taller than the tower on which it stood, and it gave a remarkable character to the appearance of the building.

Colonel Bramble spoke of the resemblance between St. Mary's tower and the tower of old Bedminster parish church, now pulled down. Speaking of the roof, he said there was one typical style all through Somerset which had got to be known as the Somersetshire waggon roof. There they had a Somerset waggon roof and a great deal besides.

The Rev. J. Edwin Odgers, lecturer on ecclesiastical history at Manchester College, Oxford, spoke of the ceremonies which formerly took place in the church between Good Friday and

Easter Day. A sepulchre was set up in the church, watchers were appointed until the Sunday, when a curtain was drawn back revealing the figure of the risen Saviour.

Mr. Charles Major also made some interesting remarks.

Dr. Winterbotham dissented from the view of Mr. Buckle that the altar-piece belonged to the Italian school, and said he considered it was a specimen of the Flemish school. It was said to have been taken from a privateer, and it had been inspected and valued by Sir Joshua Reynolds.

It was mentioned that the Corporation annually insured the picture in 10,000*l*.

The Rev. H. Bircham, vicar of the church, said the registers were very interesting indeed, and Mr. Lockyer, the parish clerk, would have great pleasure in showing them as well as the communion plate. Alluding to previous remarks, he said the chancel did not belong to the Corporation, who were only the lay rectors. With regard to the picture, he did not believe that that belonged to them either. It had been there many years, and he doubted their having the slightest power over it, although he did not want to reopen the question.

The Rev. F. W. Weaver said the churchwardens' accounts, which belonged to the Corporation, went back to 1300, and they were some of the most interesting in the West of England.

The party next wended their way to Blake Street, to inspect what is acknowledged to have been the birthplace of the famous Admiral Blake. For some years past it has been the residence of Miss Parker, niece of the late Mr. George Parker, author of a brief history of Bridgwater and other works, who purchased the property in question. Mr. Parker, a nephew of the deceased gentleman, received the party on their arrival and escorted them through some rooms and into a garden at the rear, adjacent to what is locally known as "Mill tail," and referred to as such in Domesday Book. It was admitted that the premises had undergone very extensive alterations, but there were traces of ancient remains, and in particular Mr. Parker pointed out those of an old window and fireplace which undoubtedly constituted a portion of the original building.

The party next directed their steps to the Western Quay, and here they were shown the only remaining traces of Bridgwater Castle, consisting of a massive stone archway, formerly a portion of an old water-gate, this being situate at the entrance of some bonded cellars in the vicinity of the Custom House. This was viewed with a good deal of interest, and although no public observations were offered thereon, several members indulged in a retrospect of recorded events connected with the siege of Bridgwater and its heroic defence, and expressed surprise that the castle had been so completely dismantled that all other traces of it had disappeared.

At 4.30 the members again assembled in the town hall at a meeting, at which papers on local subjects were read and discussions took place. Mr. E. J. Stanley, M.P., again presided.

Index to Collinson's "History of Somerset."

The President first called upon the Rev. F. W. Weaver, M.A., to make a statement with regard to the index to Collinson's "History of Somerset."

The Rev. F. W. Weaver said he was bringing out in a form uniform with the Collinson's "History" an elaborate index to the whole of the three volumes. The index had now gone to the letter H, and in that connection of the work he had received valuable help from the Rev. E. H. Bates. Those who used the index would find it valuable when they wished to see what Collinson really said. He sincerely hoped that those who had not subscribed would give their names to Mr. Bidgood. The price of the work was 15*s*., and he hoped it would be ready by next Christmas.

Mr. Hobhouse said they were indebted to the two gentlemen who had undertaken the work, and appreciation of their efforts should be shown by purchasing the work.

A Photographic Survey of the County.

Mr. H. C. Bothamley read a paper on a photographic survey of the county of Somerset. He said the importance of photographic surveys, by which was meant the systematic collection of photographs of every place and every object of archaeological or historic interest, was becoming widely recognised. The matter had been brought before the Society on several previous occasions, and although the action of the council was sympathetic, the sympathy was not of an active kind, and the matter was dropped for a time. Recently the whole question had entered upon a new phase. The importance of the work had been officially recognised by the authorities of the British Museum, and the Museum was willing, under certain regulations, to take charge of the results of such surveys, and to store them in such a manner that they might be accessible to the general public. A National Photographic Society had been founded under the presidency of Sir Benjamin Stone, and its object was to encourage the organisation of photographic surveys, and to formulate rules and recommendations so that the surveys might be carried out in a fairly uniform manner throughout the whole country. The collecting of

the work, however, must be done by local branches of the National Society. It was highly desirable that there should be a local collection in each county under the custody of some responsible body, municipal or otherwise. He ventured to think that no associations could more appropriately take up the work of organisation of surveys than the county archaeological societies. So far as Somerset was concerned, the council of that Society had expressed itself ready to take charge of the results. The object was to excite interest of a somewhat more active and productive type, and co-operation in the organisation and carrying out of the work. If it were admitted that a photographic survey of the county was desirable then the sooner it was begun the better. Many objects of great historic interest were in constant danger of being destroyed, leaving no record except some drawing which might do credit to the imagination of the artist, and was of no value at all for the purpose of exact knowledge. In Somerset a considerable portion of the more interesting objects were of a domestic character—old houses and the like—and those were the objects in the most danger of destruction. In many localities, including Somerset, a large amount of the actual photographing necessary had already been done, and it only remained to collect, classify and catalogue the results. Somerset was exceptionally fortunate in the fact that there were in existence a large number of negatives of objects which had since disappeared, and they therefore had very special value. Archdeacon Ainslie, who was a photographer in the early days of the art, had a negative of the tower of St. Mary's Church, Taunton, before it was rebuilt, and in the Society's museum at Taunton there were a considerable number of prints of old houses, many of which had been greatly altered or destroyed altogether. The chief point for the consideration of the Society was whether a committee should be appointed to aid the proposal, and as to the necessary expenditure the point was whether the general fund would bear a small annual charge to meet the expenses. He urged that the subject was one which the Society might appropriately take up, and he trusted that a committee might be appointed as soon as possible, so that although Somerset could not be the first county to organise a photographic record of its objects of interest, it might yet be one of the first in initiating such, and, one would hope, in completing a work which in the mind of many was of a great deal more than local interest and importance.

Mr. Hobhouse thought it was a very proper object for the Society to take up, but the proper mode of procedure would be to refer it to the executive committee to see if they would take it up in conjunction with certain other bodies, and whether it would be desirable for them to make a small grant to cover initial expenses. It was clear that no large grant could be made at present, but Mr. Bothamley had suggested voluntary subscribers if sufficient could be found to set the ball rolling. He would like to know the extent of Mr. Bothamley's proposition before referring it to the council to consider.

Mr. Winterbotham said if the Society did not see its way to granting any large sum of money it could give an expression of opinion that the suggestions thrown out by Mr. Bothamley were worthy of consideration. They had not the funds to make themselves a Society for the purpose of protecting national monuments, great and small, in Somerset, but the idea that they could keep a faithful representation of what they had before the year of destruction came was one within their grasp and means, and although the Society might not feel themselves able to contribute largely, their protection thrown over the idea would enable it to advance, and many of them would be glad to form a subsidiary society which would aid such matters.

The Rev. F. W. Weaver said there was a valuable collection of photographs of old churches obtained by Mr. Gill, formerly of Bridgwater, in existence, but they were in possession of a certain firm, who, possibly, would part with them to the Society for a reasonable sum.

The Rev. J. Worthington said it was entirely a question of finance, but if common action were undertaken he felt sure the council and members would support the matter right heartily.

Mr. Bothamley did not anticipate the expenses would be very large. Mr. Hobhouse wished to know the extent of his proposition. His suggestion was to first obtain photographs of domestic objects which were liable to disappear, and afterwards those subjects which were less liable to alteration.

The Rev. J. E. Odgers then read a paper on "The Bridgwater Academy, 1689-1748." He began by pleading for the extension of the operations of the Society to the domestic antiquities of the last century. The domestic history of England from 1688 to the accession of George III. was much neglected. The materials existed in vast stores of pamphlets and archives. They were especially interesting in the West of England, which was a stronghold of Whiggism and Dissent, on which Tory Governments kept a jealous watch. Here persecutions of Dissenters were very severe, and after the passing of the Toleration Act chapels sprang up at once. The old building called Christchurch, or "the '88 chapel," in Bridgwater, must have been fairly in course of erection before the Act passed which licensed it. But the liberty of teaching was

strangely overlooked in the passing of the Toleration Act and the enactment of the "Five Mile Act," that no Nonconformist minister nor any member of his family might keep a school, and this remained unrepealed. The well-to-do Nonconformists wanted university education for their sons, and dissenting academies were formed. With the accession of Anne and renewed petty persecution of Dissenters, an attack was made on the dissenting academies, and just before Queen Anne's death the Schism Act was passed, which was specially aimed against them. After the Queen's death, however, this Act became practically a dead letter. The Bridgwater Academy was in the home of John Moore, a Brasenose man and an ejected minister, of Haselbury. Five years after the great ejection and in 1679, he settled in Bridgwater as pastor of the church founded by Norman. The teaching was in the hands of his two sons, who were both M.A.'s of Edinburgh. He thought the academy teaching began in 1698. In the time of William III. John Moore was arrested at the foot of his pulpit stairs, and his two sons had to go into hiding. He had the names of sixty-five pupils of this academy, the sons of dissenting gentlemen who were excluded from the Universities. Among the names locally connected were two Normans, one a grandson of John Norman and grand-nephew of Blake, Speke of Jordans, the Battens of Yeovil, Ostlers of South Petherton, Baker, Keech and Rutter of Ilminster, the Rev. Charles Gifford, afterwards of Chard, and many connected with the dissenting ministry, including a son of John Flavel, Dr. Samuel Chandler of London, Dr. J. Milner, who became the head of a school at Peckham in which Goldsmith was an usher. Peculiar interest attached to one man, Simon Brown, native of Shepton Mallet, distinguished as a writer of poetry and hymns, and a combatant against the English Deists. He suffered under a strange delusion that God had annihilated in him all reason, and that he was no longer a mortal agent and had no human soul, though he might seem rational to other people. The dissenting academies of those days were framed on the models of the Universities, all the lectures being in Latin and Latin text-books being used.

The reading of this paper concluded the meeting.

In the evening there was a very large attendance in the town hall for the purpose of hearing a paper on "Admiral Blake" read by Captain Montagu Burrows, R.N., Chichele Professor of Modern History in the University of Oxford, and Fellow of All Souls, and by Mr. W. L. Winterbotham on "Blake's Charities."

(To be concluded.)

THE SITES FOR GOVERNMENT OFFICES.

THE select committee of the House of Commons, consisting of Mr. Smith-Barry, Mr. John Burns, Mr. Chancellor of the Exchequer, Sir Charles Dilke, Mr. Disraeli, Mr. Akers-Douglas, Mr. Herbert Gladstone, Sir James Kitson, Mr. Legh, Sir Herbert Maxwell, Mr. Molloy, Sir Stafford Northcote, Mr. Whitmore, appointed to inquire into and report upon the manner in which the sites available for the erection of the new buildings required for Government offices may best be appropriated for that purpose, have agreed to the following report:—

In continuation of our report, dated July 23, 1896, we beg leave to state that we have taken further evidence upon the plans laid before the committee last year. Having regard to certain criticisms made from an architectural point of view upon those plans, we have thought it well to examine representatives of the Council of the Royal Institute of British Architects and other qualified members of the profession. Various alternative plans have been submitted to us by these gentlemen, but whilst we have availed ourselves of some of their suggestions, we have felt unable, owing partly to the enormous cost involved and partly to other considerations, to recommend their schemes generally for acceptance.

Upon a review of the whole evidence we have arrived at the following conclusions:—

We are of opinion that the new public offices on the Parliament Street or Great George Street site should be erected mainly on the lines of plan No. 1 in the appendix to the report of last year, with a frontage in a line with the frontage of the Home Office and parallel to the east side of Parliament Street; but we recommend that the south-eastern corner of the new building should be square and not rounded. The land between this new frontage and the present west side of Parliament Street would, if this plan were adopted, become part of the public street, and in our opinion there is no need to make special provision for separating the traffic at this point. It appears to us reasonable, in view of the great metropolitan improvement here to be carried out at the cost of the Government, that the London County Council should be requested to consider whether they should not put into operation the powers possessed by them under the Public Offices (Westminster) Site Act of 1896, and contribute a share of the total value of the land, which under this scheme would become part

of the public street. We recommend the appropriation of this site for the Board of Trade, the Education Department and the extension of the Local Government Board.

As regards the Whitehall site, having considered the alternative schemes for the War Office which have been placed before us this year, we adhere to the recommendation made in our interim report, being satisfied that a building satisfactory in appearance and accommodation can be erected on that site within its present boundary lines; and we are of opinion that the details as to the arrangements of buildings, courts, &c., should be entrusted to the discretion of the Office of Works, in conjunction with the architect selected. We think that a sub-way should ultimately be formed under the street between the War Office and the Admiralty.

Schemes have been submitted to the committee by the Royal Institute of British Architects and by Colonel Edis, for a widening of Charing Cross and of the northern part of Whitehall; but we cannot recommend that the taxpayers should be asked to bear the cost of this metropolitan improvement, which if undertaken comes more properly within the duty of the local authorities. We, however, strongly advise that the Mall should be opened into Charing Cross on the north side of Messrs. Drummond's bank.

We do not contemplate the passage of any other than light traffic through the Mall, and are satisfied that the skill and experience of the police would supply satisfactory means of overcoming any difficulties of traffic which might to some extent follow such opening.

We think that no decision should be arrived at as to building on the triangular site in Spring Gardens until the houses standing there have been removed, and the ultimate requirements of the Admiralty considered.

We recommend that Nos. 11 and 12 Downing Street, occupied respectively as a residence for the Chancellor of the Exchequer and as an office for the Patronage Secretary to the Treasury, should be removed as unworthy of the site they occupy; but we are of opinion that the principal block of No. 10, the historic residence of the First Lord of the Treasury, for reasons of practical necessity and on account of its associations, should be retained, the Downing Street front being masked by erecting a new building with a good architectural façade, and the Park front being cased in stone so as to harmonise with the north and west fronts of the old Treasury buildings, and the garden ground being enclosed with a screen or railing of handsome design.

We do not recommend any further building on this site. We are of opinion that whatever other office accommodation is required, which cannot be conveniently found in existing Government buildings, should be provided for by an extension of the Great George Street site in the direction of Delahay Street and St. James's Park, in which case some readjustment of the arrangement at present shown in the plan of the Office of Works might have to be made.

The following paragraph which was in the draft report was not agreed to:—

To have a second opening from the Mall, south of Messrs. Drummond's Bank, appears to us to be unnecessary, and any new road from Charing Cross to the Embankment should fall into the category of metropolitan undertakings.

SCIENCE AND ART SCHOOLS.

THE forty-fourth report of the Department of Science and Art to the Committee of Council on Education was issued on Saturday. This shows that in 1887 the science schools numbered 1,684, the classes 6,300 and the students under instruction 103,088. In 1896 the figures were 2,583, 10,300 and 196,185 respectively. Of the 2,583 schools in 1896, 144 were organised science schools with 16,654 students. This is a considerable increase on the preceding year.

The number of students who came up for examination from these schools was 91,300, a decrease of 16,863 on the previous year. Besides these, 8,518 self-taught students and pupils from classes not entitled to claim payments on results presented themselves for examination. 30,066 out of the 99,818 students who were examined were successful in passing in one or more subjects, and of these 16,551 were successful for the first time. In the previous year 52,079 were successful, and 22,542 for the first time. For the year 1896 the payments to science schools, exclusive of those made to training colleges, on the results of examinations, and on attendances, &c., amounted to 157,916*l*. The corresponding amount for 1895 was 142,542*l*. In the art division the report states that during the year ending August 31, 1896, 20,161 elementary day schools with 2,250,070 scholars were taught drawing and examined under the regulations of the Department. This was an increase of 263 schools and of 57,820 scholars, as compared with the numbers in 1894-95. Besides the scholars who were taught in the drawing standards, 18,209 pupil-teachers and ex-standard scholars were examined in drawing, of whom 8,859 were successful. The grants for drawing in 1896 to

elementary day schools amounted to 176,224 $\frac{1}{2}$, in 1895 to 164,494 $\frac{1}{2}$, and the number of schools gaining the awards fair, good and excellent respectively was as follows:—In 1896: Fair, 848; good, 12,850; excellent, 6,391. In 1895: Fair, 1,484; good, 13,323; excellent, 5,051. Eight hundred and seventy-three evening continuation schools were also examined in which 40,459 scholars were taught drawing, the grants earned by them amounting to 2,105 $\frac{1}{2}$. In the previous year the number of evening continuation schools taking drawing was 698, with 37,460 scholars, the grants amounting to 1,664 $\frac{1}{2}$. Classes for manual instruction in connection with 1,069 elementary day schools were examined in the year ended August 31, 1896, and earned grants amounting to 19,530 $\frac{1}{2}$ on account of 83,220 scholars. In the previous year the number of manual instruction classes examined was 910, and the grants earned amounted to 16,307 $\frac{1}{2}$ on account of 67,470 scholars. The number of art schools and classes (including 80 science schools which take art subjects) examined in art in 1896 was 1,851, as against 1,853 (which included 91 science schools) in 1895. The number of students in 1895 was 136,768, and in 1896 146,193. The number of students who were examined in 1896 was 78,139, or two less than the previous year. The number of visitors during 1896 was 1,135,797 at South Kensington Museum and 383,709 at Bethnal Green Museum, making a total of 1,519,506. This shows an increase of 123,630 as compared with the year 1895.

BEBINGTON CHURCH RESTORATION.

BEBINGTON CHURCH, one of the most ancient and beautiful churches in Wirral, is undergoing restoration. A village committee has been appointed by the churchwardens to determine what shall be done, and it has been determined to make extensive alterations in the structure. About fifty years ago the church underwent restoration, and several internal arches were constructed of very good design, but partly of plaster. For these it is proposed to substitute an entirely new design of decorative timber framework. The plaster on the walls of the nave is to be stripped off, and the rough rubble wall pointed, so as to make its construction conspicuous. The chancel-roof and those of its aisles are to be boarded and covered with felt and decorations of a tasteful sort, for which the able architect under whom the committee and churchwardens have placed themselves is considered to be a master. These alterations (writes a correspondent) will cause a complete transformation in the present appearance of the church, which (picturesque as its present appearance is) does not approve itself to the ideas of restorers, chiefly on account of the materials with which it was repaired at previous restorations. Some of the ancient portions of the church removed at the former restoration are still in existence and in good condition, but the taste of the churchwardens and committee seems to favour an entirely new design, at all events for the junction of the nave and chancel. Whether such extensive changes are called for may be a question, but some repairs are needful. A few decayed pieces of timber from the roof have been selected for exhibition at the doors of the church, which seem to prove that partial repair was desirable if not urgent. Whether more alterations should be made rests with the judgment of the committee and their architect, and it is to be hoped they will exercise it with discretion, as the responsibility of dealing with monuments of antiquity is no light one, and very few of the modern modes of altering and adorning them are not liable to serious criticism, and should always be in conservative and competent hands.

The Nude Greek in Art.

SIR,—Being one of those whom your correspondent "Ronald Kelly," in his letter which appears in your issue of August 6, designates as "brazen-faced apologies for girls and women," I feel I must reply to it, which I trust, out of fairness to my fellow-students and myself, you will publish.

Mr. Kelly heads his letter "The Nude in Greek Art," but he displays such a lamentable amount of ignorance of art, and the steps necessary to become an artist, that I am afraid all art is Greek to him.

He writes, "I was struck with the unsoundness of your arguments," &c. His letter is so insulting to lady art-students that I should like to strike his head with something—a mahlstick would do, only one or the other might get broken, and perhaps it would be the mahlstick, which would be a pity, as that at least is of some use.

Of course a sculptor does not look at a figure from a medical point of view; to arouse his enthusiasm a figure must be physically beautiful, whereas a medical man would take a keener interest in one diseased.

He also says, "I have always esteemed morality as the foundation of civilisation." There have been, and are now living, artists who by their work have given us sermons on morality which are for all time, and, strange as it may seem to Mr. Kelly, these men have studied the very figures he considers so objectionable, but they studied humanity with eyes wide-open, wide enough to detect the true from the false.

It is difficult to think that he is the high-souled creature he would have us believe. Does he not know that it is absolutely necessary for an artist to study from the nude even if all his finished work consists of draped figures? Surely no one with any fine feeling, and possessed of a manly spirit, would so far forget himself as to apply the expression "brazen-faced apologies for girls and women" to a body of women who socially, intellectually and morally reach a high average, simply because, having mapped out a career for themselves, they go to study in a building which contains the finest material for them, but a building which, being thrown open to the public, admits such narrow-minded creatures as your correspondent.

He seems anxious to have all figures draped. Imagine Apollo with a tall hat, tail coat and an umbrella, or Venus gowned (not an evening gown, please). They look beautiful now, but, brought up to date in the above style (as your correspondent seems to think they should be), I think they would look a very fast set.

Before Mr. R. Kelly again writes upon art and morality let him climb down from the high pedestal upon which he has placed himself and study art and his fellow men, and drop his abusive literary style. Then, and not till then, will he write anything worth reading.—I remain, yours faithfully,

August 9, 1897.

A LADY ARTIST.

GENERAL.

The Prince of Wales, as representative of Her Majesty the Queen, will lay the foundation-stone of the new Christ's Hospital Schools at Stammerham, near Horsham, on Oct. 23, the anniversary of the founding of the schools in Newgate Street by Edward VI.

The Department of Science and Art has received, through the Foreign Office, a copy of a despatch enclosing a translation of a Royal decree for the holding of an exhibition of Spanish industries in the Palace of Arts and Industry, Madrid, this year. The exhibition will be opened on October 20.

The Members of the Birmingham Architectural Association have just returned from their annual sketching expedition, which is arranged to provide students with opportunities for studying examples of ancient and modern architecture which may be of service to them. One day was devoted to a careful study of Tewkesbury Abbey, whilst the noteworthy architectural structures in the district of Bredon, Pershore and Upton-on-Severn were inspected during two days. The fourth and last day was devoted to Northampton Court.

A Statue of Charles Darwin, by Mr. Horace Montford, was unveiled in Shrewsbury on Tuesday. The figure, which is of bronze, is seated. It was presented by the Shropshire Horticultural Society, and has cost about 1,000 guineas.

An Exhibition of works by the late Robert Atkinson, Thomas Sutcliffe, Atkinson Grimshaw and Edward March, will be held in the Corporation Galleries, Leeds, during the months of November and December. It is to be hoped the exhibition will be more successful than the Spring Exhibition, which involved the ratepayers in a loss of about 150 $\frac{1}{2}$.

The East Sussex Council have resolved to give notice of their intention to withdraw in 1902 from any partnership with the Brighton Town Council in the Hayward's Heath Lunatic Asylum. A new asylum will have to be erected, at a cost estimated at from 120,000 $\frac{1}{2}$ to 132,500 $\frac{1}{2}$.

Muckross Estate, Killarney, has been selected as a site for a royal residence, and a substantial sum is said to have been offered for the property.

Miss Talbot, of Margam Park, who has already provided several churches for the diocese of Llandaff, has just built a very handsome one dedicated to St. Theodore, at Port Talbot, in memory of Mr. C. R. M. Talbot, M.P. (so long the father of the House of Commons), Mr. Theodore Talbot, and Miss Olive Talbot.

The Results of the Glasgow School of Art three days' examination in advanced architectural design, held in May last, have now been received from the Science and Art Department. Twelve students of the Glasgow School of Art entered for the examination, and all have been successful, five passing excellent, five first-class and two second-class. A further award has been made to the school of a bronze medal for a first-class honour in building construction.

The Architect.

THE WEEK.

THE annual meeting of the British Archæological Association began in Conway yesterday, under the presidency of Lord MOSTYN. The members visited the castle, the parish church and the abbey, and in the evening the President's address was delivered. On to-day St. Asaph and neighbourhood will be seen, and on to-morrow Carnarvon. The programme for next week comprises visits to Bangor Cathedral, the castle, the British camp, the Roman station of Conovium, Caerhun, Bettwys-y-Coed, Llanrwst Church, Gwydir Chapel, Gwydir Castle, St. Tudno's Church on Great Ormes Head, the sixteenth-century farmhouse at Penrhynside, St. Trillo's Chapel and Plas Fynach. Among the papers to be read at the evening meetings are the following:—"Some Ancient MSS. relating to North Wales," by Mr. WALTER DE GRAY BIRCH; "Rhuddlan Castle," by Mr. C. H. COMPTON; "Clynnog Church," by Mr. CHAS. LYNAM; "The History of Rhos Rhuvoing, the Lordship of HENRY DE LACY," by Mr. MEREDITH J. HUGHES; "Caves and Passages under the British Camp of Pen-y-Gaer, Conway Valley," by Lady PAGET; "Some Early Settlers near Conway," by Mr. J. S. PHENE; and "Conway Castle," by Colonel G. LAMBERT.

SIR JOHN EVANS has had a long practice in addressing assemblies of men of science, and it was, therefore, to be expected that his presidential discourse at the meeting of the British Association in Toronto on Wednesday would be successful. To some extent his appearance in the presidential chair was anomalous, for it was likely to give an erroneous notion of the aims of the Association. As announced by the title, it is the British Association for the Advancement of Science; the present and the future concern it, not the past. But when by the exercise of no little diplomacy an anthropological section was formed in the Association, scope was given for the display of researches in prehistoric archæology like those in which SIR JOHN EVANS has been engaged.

A STUDENT who occupies himself with the past could not speak with authority about the advancement of the various branches of science unless he relied on information supplied to him. What SIR JOHN EVANS attempted was more satisfactory. He was able to demonstrate that the various sciences as they advanced, and by means of their discoveries, could afford interpretations of archæological difficulties which were beyond the skill of the ordinary archæologist. One passage will exemplify the President's mode of reasoning:—"Every reader of VIRGIL knows that the Greeks were not merely orators, but that with a pair of compasses they could describe the movements of the heavens and fix the rising of the stars; but when by modern astronomy we can determine the helical rising of some well-known star, with which the worship in some given ancient temple is known to have been connected, and can fix its position on the horizon at some particular spot, say, 3,000 years ago, and then find that the axis of the temple is directed exactly towards that spot, we have some trustworthy scientific evidence that the temple in question must have been erected at a date approximately 1,100 years B.C. If on or close to the same site we find that more than one temple was erected, each having a different orientation, these variations, following as they may fairly be presumed to do the changing position of the rising of the dominant star, will also afford a guide as to the chronological order of the different foundations. The researches of Mr. PENROSE seem to show that in certain Greek temples, of which the date of foundation is known from history, the actual orientation corresponds with that theoretically deduced from astronomical data. Sir J. NORMAN LOCKYER has shown that what holds good for Greek temples applies to many of far earlier date in Egypt, though up to the present time hardly a sufficient number of accurate observations have been made to justify us in foreseeing all the instructive results that may be expected to arise from astronomy coming to the aid of archæology." It was likewise explained

how the other branches of science can become efficient auxiliaries to archæology, and afford to it that precision which is demanded if it should claim to be a science. But we intend next week to give a report of the address.

THERE could hardly be a more opportune time for discussing in Canada the subject of education in engineering than the occasion of the visit of the British Association. On Monday, Tuesday and Wednesday of the present week the Society for the Promotion of Engineering Education held its annual meeting in Toronto. The programme of the proceedings will suggest the comprehensiveness with which the subject of education was treated. It runs as follows:—The President's address, "The Scope and Relative Importance of Theoretical Study," by HENRY T. EDDY; "Methods of Teaching—by Text-book, by Lecture, by Design, by Laboratory, by Memoir," by W. H. P. CREIGHTON; "The Teaching of Machine Design," by J. J. FLATHER; "The Calculus for Engineering Students," by F. W. McNAIR; "The Influence of Scientific Research upon the Development of Chemical Technology," by H. BUNTE; "Chemical Engineering," by J. M. ORDWAY; "The Efficiency of Technical as Compared with Literary Training," by T. C. MENDENHALL; "A Course in French and German for Engineers," by A. N. VAN DAELL; "At What Point should Students engage in Specific Research, and how much Aid should they receive from the Professor?" by C. D. MARX; "Mining Vacation Field-Work," by F. W. DENTON; "To what Extent should Metallurgy be Taught in Mechanical Engineering Courses?" by M. E. COOLEY; "Engineering Laboratory Courses," by R. C. CARPENTER; "Elective Studies in Technical Courses," by H. L. MUNROE; "Manual Training for Artisans," by C. M. WOODWARD; "Manual Training in Public High Schools," by T. W. MATHER; "Graduation Theses; their Preparation, Form and Preservation," by IRA O. BAKER; "Agricultural Colleges; their Function with Relation to Engineering," by C. S. MURKLAND; "The Education of the Electrical Engineer," by W. E. AYRTON; and "A Course of Study in Electrical Engineering," by R. B. OWENS. It will be remarked that the Canadian educationists do not propose to encroach on architecture, and for so good an example they merit praise.

THE French are disposed to take up the King of ABYSSINIA with alacrity, especially as they believe he is not too friendly to British visitors. In such cases the newly adopted favourite is always supposed to possess wonderful qualities which will account for his preference of France to England. King MENELEK is therefore described as an architect. M. LAGARDE, the French plenipotentiary, says that when he was about to leave, the King brought him a plan prepared by the royal hands of a mansion which it was proposed to build at Addis-Ababa for the representative of France. It is said to be admirably arranged and combines all that architectural art and modern notions of comfort can accomplish to make the resident happy. Abyssinian houses are not remarkable for their excellence and diplomatists are not always the most trustworthy critics.

THERE will be, according to report, an important competition shortly in America which will not be confined to the numerous representatives of all nations which are to be found throughout the States. The conditions of the competition are to be arranged by M. GAUDET of Paris, and on the jury will be a deputed representative of France, Germany, Great Britain and the United States. As the building or buildings will serve for the University of California that institution will also have its jurymen. The preliminary arrangements were undertaken by Mr. REINSTEIN, the University Regent, and Mr. MAYLOCK, of the Agricultural Department. Several architects, it is understood, will be invited to send in sketch designs, and will be paid for their labour. At least ten plans will be selected for further elaboration. The authors will have the privilege of nominating four additional jurors, and the second competition will therefore be determined by nine judges. California, according to many observers, is to be the "happy land" of the future, and it is well to provide for its destiny with becoming liberality, but the grandiose character of the forthcoming competition is probably owing to an American lady becoming responsible for the expenses.

THE SCIENCE AND ART DEPARTMENT'S REPORT.

THE pages of the forty-fourth report of the Department of Science and Art present the usual array of figures, but it is doubtful whether any outsider can infer from them what is the extent of last year's progress. It may be assumed that the majority of officials are not more competent to determine results. The reason is that of late the system of teaching is undergoing modifications, and it is almost impossible to point to data which can be considered to have permanence enough to serve for any one who would wish to employ statistics as evidence. For example, in one table we find it stated that in the year 1896 the papers worked in science numbered 152,630, while those passed were 62,886. In the preceding year the respective numbers were 202,868 and 85,303. It is not until we go back to 1888 that we find so small a number of papers as in 1896, and there is no precedent in ten years for such a disproportion between papers sent in and papers passed. Out of 127,875 papers no less than 88,405 passed in 1887. The natural conclusion would be that unless the standard was elevated, or the students had degenerated, there was less success in 1896 than in 1887. But the report warns us that the figures are not comparable. From 1889 up to 1895 geometrical drawing was treated as a science subject, but in 1896 it was again included among art subjects. All that is necessary in order to mystify the public is, therefore, to take one of the numerous subjects which can be called science or art, and, according to the division in which it is placed, the totals will rise or fall. When there is so much elasticity it is vain to expect precision. But apparently there is no manipulating method which will veil the stern fact that expenses are increasing. Each individual science student in the schools in 1895 cost the country 14s. 9d., but in 1896 the cost was 17s. 7d. For each student in each subject last year the cost was 12s. 3½d., while in the preceding year it was 9s. 1¼d. Art is imparted on more economical and it must be said less variable terms. Embryo English artists can be trained at the rate of 1s. 9d. a head; in Scotland 1s. 8½d. is enough; while in Ireland they are turned out for 1s. 6½d. An economist will ask why the Irish method of using the money is not more generally adopted?

If the figures which have cost so much to collect, tabulate and print are not "comparable in all respects," what is to be said of the examiners' reports? The procedure followed in assessing the value of the students' works, if it were fully described, would form an amusing article. Some judges appear to be always fortunate in receiving a multitude of satisfactory attempts. There are others whose reports suggest that they wish they were endowed, like the sad-eyed justices of the hive, with power to deliver to executors pale the lazy yawning drones. The English language, too, is limited in adjectives, and the examiners are generally afraid to display acquaintance with them. In consequence, when year after year the work in any one of the wide sections of science is characterised as "on the whole good," or "fairly well," or "not distinctly good," or "not very high," or "of average merit," or as poor, satisfactory, weak, very low, &c., it is difficult to resist asking what is the significance of the scale of merit which is graduated so indefinitely? If the work is "poor" in one year and "weak" in another, are we to conclude that science classes are improving, or the reverse?

Reports of Government departments would hardly be tolerated unless there was a more than diplomatic vagueness about the statements, and the South Kensington annuals have the quality in perfection. It is evident, however, that plain speaking has at last some representatives. In the last report it is found in the remarks about school and college buildings. The Royal College of Science, which as the work of an official who was not a civil architect, was long bepraised as an example of what the Department could accomplish by its own staff, is one of the structures which are not spared. The Professor of Chemistry says of his laboratories:—

Frequent reference has been made in earlier reports to the defective ventilation of the laboratories, and the Professor regrets that no serious steps have yet been taken to remedy a state of things which, in the winter months, produces much inconvenience and must be frequently prejudicial to health. In

the South Laboratory this is the more noticeable, since not only are the draught cupboards most inefficient for the purpose of preventing acid and other fumes from finding their way into the laboratory, but the sulphuretted hydrogen cupboards are also actually in the laboratory itself, and this offensive gas frequently passes into the atmosphere of the laboratory and balance-room almost as much as into the flues provided for its escape. There can be no doubt that the students whose benches are near to the sulphuretted hydrogen cupboards are exposed to the risk of injury to their health, since the amount of this noxious gas in the atmosphere of this portion of the laboratory is sufficiently large, on an ordinary working day in the winter term, to make it impossible to carry out satisfactorily the estimation of silver, copper and lead, owing to the sulphide formed in solutions of their salts by contact with the air during the ordinary analytical operations. Ventilation, in the proper sense of the term, does not exist. There are no means either for exhausting the foul air from the laboratories or for forcing fresh air into them, and the only way of changing the air is by opening the windows and thus obtaining a through draught—a procedure which, in the winter months when the laboratories are most crowded and most in need of ventilation, is a fruitful source of colds and chills, as well as of inconvenience to the workers using gas flames for heating purposes.

When the Royal College of Science is in so discreditable a condition it is hardly to be expected that in minor laboratories there would be more respect for sanitation. We are consequently little surprised when we find one of the senior inspectors saying:—"I regret to find that in many new laboratories architects and makers of laboratory fittings are content to reproduce the old conditions without caring to ask advice in the former case, or to alter their stock patterns in the latter. I have seen during the year at least a dozen new chemical laboratories without a single sink placed in a proper position, or a single fume closet suitable for anything but a sulphuretted hydrogen apparatus. Schools which thus blindly take whatever makers choose to provide cannot surely feel surprised when on inspection the arrangement or fitting of the laboratory is adversely criticised. The responsible chemistry or physics teacher is often the last person consulted as to the requirements of his own special department." The inspector ought to have known that architects are not always called in to design laboratories, and when they are it is considered necessary to scrupulously follow the instructions of somebody who claims to be an expert. There is also supposed to be an official type, and that any departure from it will have an injurious effect on the future success of the school. The power possessed by the representatives of science in such cases is suggested by another report, where it is said, "In not a few towns the technical committees appear to consider technical education to consist mainly in the teaching of trades, languages, cookery, dressmaking, shorthand, &c., and have ignored the art school as outside their domain." The applicability of drawing in the trades and crafts is not considered. Hertfordshire is a notorious offender, for in the whole county there is not a single girls' school or department in which drawing is taught.

The question of providing technical schools of a satisfactory kind will have to be met in a short time if there is to be any advancement in technical education beyond the most elementary stage. It appears that the secondary schools of Surrey and Hampshire have at least one laboratory, and some have workshops also. But many of those schools have been largely endowed, and it is not very difficult for them to provide the apparatus and accommodation which are demanded. But there are also schools which have no aid of that kind, no dead hand regularly bestowing gold, yet these schools might be able to take more advantage of instruction than their more fortunate rivals. But the county councils appear to have favourites, and where possible departmental schools secure the larger share of grants. Why should Portsmouth, out of a grant of 3,000l. a year from the county council, bestow no more than one donation of 40l. on the promotion of science in the local grammar school, where the money would be wisely applied, and where the funds are always insufficient? In fact, the money question is too influential in some of the schools. Some organised science schools, says one inspector, have actually deleted from their time-tables any subjects but those capable of earning money grants. The students take the same view, for we are told that "in the evening school the bread-and-butter value of a particular science will for a

long time be the chief incentive to its study, whatever inducements teacher or governing bodies may hold out to the contrary." In Ireland, which seems to be ruled by some principle of contrariness that is omnipotent, the money allotted to science is devoted to a sort of literature. The Irish inspector writes :—

The course of study is framed at the beginning of the school year, and executed during the year, so as to earn the maximum grant from the Board of Intermediate Education. The results paid and the prizes awarded by this Board are so liberal that teachers and pupils alike are focussed on them throughout the session, so that, naturally, only those subjects which pay, and pay best, for the Intermediate are taken up in the schools. Now the Intermediate Board makes practically no provision for instruction in science or in art—if elementary mathematics be excluded—almost the whole bulk of their grant being awarded to literary subjects. Science does not "pay," and the schools cannot be expected to take it up until it does pay. Thus it is clearly established that not only has no portion of the large sum of money received under the Local Taxation (Customs and Excise) Act been spent in the encouragement of science in Ireland (as it is in England), but that it is so disbursed that the very reverse effect is produced. Under these circumstances, it is not strange that in Ireland we have no organised science schools, no practical physics in the schools, and hardly any practical chemistry. In most of the schools where science classes are held in connection with the Department, the teaching consists of mere "lesson-hearing," and no attempt is made to illustrate the subject by experiments performed before the class. The apparatus in many cases is not even exhibited to the class, as some teachers consider the pictures in the text-books more instructive and less troublesome.

When science is taught in so mirthful a manner, who can wonder that so few Irish names are found among the inventors in the patents list, or that the contributions from Ireland to scientific journals and transactions should be so rare? The Irish system represents the most useless teaching. It deserves to be contrasted with the system which the inspector of the Oxford division sketches as absolutely necessary if the country is to hold the rank which is desirable. He says :—

If science and art and technical knowledge in this country are to be brought to anything approaching the excellence which is attained on the Continent, where I have had considerable opportunities of studying the systems which prevail, it is imperative that in each district of the extent of the average county there should be erected, and maintained in a high degree of efficiency, at least four central institutions of the nature of first-class science and art and technical institutes; these should be provided with lecture rooms and laboratories for the teaching of pure science, which must always form a large part of the knowledge imparted, as a fundamental basis upon which all future specific technical instruction must rest, with adequate art rooms, with mechanical and technological workshops and laboratories, and with rooms available for the colloquial teaching of modern languages and for commercial subjects. The pure science rooms should include not only a chemical and a physical, but a biological laboratory, the latter being especially useful for elementary instruction in botany and physiology. In addition to these institutes for the benefit of both day and evening students, there should be, either in connection with or in close proximity to each of such institutions, a really good secondary school, where, in addition to the usual literary subjects, including modern languages taught to be spoken as well as read and written, the importance of which is not to be overrated, a considerable proportion of pure science should be practically taught; a school, in fact, of the type of the better organised science schools. The elementary schools should be made to lead more directly to the spending of at least two years in such secondary schools, after which two or three more years' work in the evening classes of the science and art and technical institutes would be spent with the maximum of advantage, and if these latter institutes approached the high order of efficiency which is so desirable, this country would soon take rank with Germany in the training of its youth for the important labours of their maturer life, and with the final polish, and a training in original investigation given to as many of the most successful students as possible in the University colleges, we should have nothing to fear from foreign rivalry.

It would be possible to do much to realise the proposal if the large sums of money which were disposed of by county councils out of the drink duty were applied to the erection of suitable buildings, instead of being frittered away in a number of small grants for the purpose of teaching rustics to execute attempts in repoussé, carving and other

fashionable accomplishments. One obstacle to the arrangement is the belief that in the old days all the arts which were required by men were taught in humble rooms, or, as in Mediæval times, in shanties erected in woods. Science will not allow itself to be treated in that way. It is only in suitable buildings that she will impart the secrets which will revolutionise life. We imagine also the Department will never support with warmth any scheme of four schools per county. The rows of figures which appear in the annual reports have been always supposed to be the main support of the Department, although not comparable in all respects, and to substitute for them a few columns relating to efficient teachers and earnest students would involve more self-sacrifice than is to be found at South Kensington.

It must be felt also on reading the report that whether the money voted for science and art is expended in the support of a comparatively few high-class schools or colleges or distributed among many village schools there will still be waste. Owing to the want of some power that can exercise control throughout the country, educational institutions appear to be undoing rather than co-operating in common work. Birmingham, for example, has an endowment which enables about 3,500*l.* a year to be spent on two high schools and seven grammar schools. According to the inspector, "Not one of these schools is conducted on the lines of a modern scientific school; and, considering the requirements of the city's large and varied industries, there is little doubt that a large proportion of the children who attend these schools would be more benefited by such an education than they are by that which they now receive. The School Board have supplied the deficiency, but inasmuch as the 'scholarship at the grammar school' is the blue ribbon of elementary education here, the organised science schools under the Board only get the rejected candidates." If we possessed an Education Department that was vigorous such an anomaly as is found in Birmingham would have a short existence. When the School Boards are allowed to adopt systems of their own for teaching drawing we have additional examples of short-sighted policy. If any of the pupils should afterwards attend the Department's art schools it will be necessary for them to unlearn many things on which time was wasted. In Birmingham the danger is obviated by making the head master of the Municipal Art School responsible for the system of teaching adopted in the primary schools. But the unity which is feasible in that case cannot be secured in the relations between the grammar schools and Board schools.

WIRING FOR THE SUPPLY OF ELECTRICAL ENERGY.

THE rules just issued by the Council of the Institution of Electrical Engineers "embody the chief precautions and requirements which the Institution considers necessary to secure satisfactory results. They have been drawn up to meet the ordinary cases of dwelling-houses, offices or business premises, but they are not intended to take the place of detailed specifications drawn up by consulting engineers to meet individual circumstances. They are confined to a statement of well-ascertained requirements, and do not recommend any special system or form of apparatus by which these may be best fulfilled."

The above are the objects of these excellent rules, which may be taken as the standard, as the gentlemen who have had the matter in hand are experienced in the carrying out and designing of wiring, some having been connected with this industry from the very commencement. We might add that there should be another object, and that is to secure their adoption by each and every insurance company.

The present number of rules, often different in essential principles, make it necessary for some one standard to be adopted, and what standard is there more desirable than that drawn up by the leading electrical engineers of the day? The point which strikes one most in reading the rules is the broad basis on which they are formed and the clearness of the recommendations.

Proceeding to the actual rules themselves, the chief point of novelty is the basis upon which the carrying capacity of wires is arrived at. For the first time in elec-

trical installation rules, the 1,000 ampères per square inch clause has been abandoned.

It is recognised that the limit of carrying capacity is that the wire shall not heat sufficiently to damage its insulation or its other surroundings. The 1,000 ampères per square inch rule does not recognise this, as a small wire will carry much more than 1,000 ampères per square inch without undue heating, while the large cables will not. This is due to the fact that the small cables have a much larger radiating surface per square inch of section than the large ones, hence they will keep cooler.

The rules as regards sectional area of cables are :—

"Their sectional area shall be proportional to the heating effect of the current required for the maximum number of lamps or other current-using apparatus that can be used simultaneously on the circuit.

"They shall be of such size that, when the maximum current is passing continuously through them, their temperature shall not exceed 130 deg. F.

"It is imperative that this temperature of 130 deg. F. should never be exceeded.

"If the maximum temperature of the British Islands be taken as 100 deg. F., then the increment due to electric heating must not exceed 30 deg. F."

A table is given showing the safe currents allowed in various sizes of wires. Column 1 gives the sizes of conductors in common use; column 2 gives the maximum current for situations where the external temperature exceeds 100 deg. F.; column 3 gives the length of wire in yards causing a drop of 1 volt when transmitting the currents in No. 2; column 4 gives the maximum current allowable in any situation; and column 5 the length of wire giving 1 volt drop. There are other columns giving thickness of insulation and minimum insulation resistances.

A few extracts from this table may be of interest :—

1 Size, S.W.G.	2 Max. current, hot places (amp.).	3 Length for 1 volt drop (yards).	4 Max. current allowable (amp.).	5 Length for 1 volt drop (yards).	6 Current at 1,000 amp. per sq. in. (amp.).
18	3.1	23	4.2	18	1.8
20	4.8	26	6.6	19	3.06
22	4.9	27	6.8	19	3.2
24	6.2	28	8.7	20	4.4
26	7.0	29	9.8	21	5.0
28	9.3	31	13.0	22	7.2
30	14.0	37	21.0	25	12.8
32	23.0	40	34.0	27	22.9
34	32.0	45	49.0	29	35.6
36	70.0	56	110.0	35	97.3
38	100.0	66	170.0	39	164.7
40	180.0	73	300.0	44	321.7
42	260	82	450	47	531.9

Column 6 has been added for purpose of comparison.

It will be seen that all sizes below A are allowed by the I.E.E. rules to carry more than 1,000 ampères per square inch in hot positions, and those below B in ordinary places, while the cables larger than these are not allowed to carry so much as this.

Another point of novelty is the recognition of lead-covered wires for house wiring. This is not provided for in any fire office rules with which we are acquainted. There are two kinds of insulation recognised:—

A. Those insulated with a material as a dielectric which is itself so impervious to moisture that it only needs further protection from mechanical injury or from vermin.

B. Those insulated with a material as a dielectric which, in order to preserve its insulation qualities, must be kept perfectly dry, and therefore needs to be encased in a waterproof tube or envelope, generally of soft metal such as lead, which is drawn closely over the dielectric.

"When Class A is used the dielectric must be perfectly damp-proof, and not in any case less in thickness, measured radially, than thirty mils. plus one-tenth of the diameter of the conductor. It should not soften at a lower temperature than 170 deg. F.

"When Class B is used the same conditions as to minimum thickness and softening temperature of the dielectric should be enforced as in Class A. Its covering should be such that a test piece cut from the conductors and immersed in water will not break down when an alternating pressure of 2,500 volts, having a frequency of from 40 to 100 periods per second, is applied for ten minutes between the conductor and the water, the test piece previous to immersion having been bent six times

(three times in one direction and three times in the opposite direction) round a smooth cylindrical surface not more than twelve times the diameter of the conductor measured outside the dielectric."

"Conductors of Class A must be protected from mechanical injury by being covered with a stout braid or taping, prepared so as to resist moisture, and must be further protected by casing or by being drawn into pipes or conduits." In the case of Class B the utmost care must be taken to keep moisture out of the wires at the ends, where in switches, &c.

There is rather a curious test for flexible cords, which stipulates that the twisted conductors shall stand a pressure of 1,000 volts between them while suspended over a pan of boiling water, not further away than 3 feet. We would not like to guarantee that 10 per cent. of the flexible cord now in use would stand this.

With regard to casing versus draw-in systems, the latter is preferred. "The use of a draw-in system in which both conductors are drawn into one strong incombustible tube or chamber, or their equivalent, is preferable to wood-casing with spaced conductors, as safety is better obtained by the use of a suitable insulation of the wires themselves than by trusting to the wood-casing or to the spacing for insulation purposes."

Bunching of conductors is allowed for circuits carrying less than 5 ampères. Conductors of opposite polarity may be bunched if enclosed in an incombustible tube or conduit. These last two paragraphs could be studied with advantage by all fire insurance inspectors, especially those who pin their faith to wood-casing, and will not hear of any other system being used.

A test for a switch which is suggested could be used with advantage is to test the switch with 50 per cent. more current and pressure than that with which it is to be used, and no arcing should result.

A point is mentioned which is often overlooked, viz. that in a three-wire system the member of the switch connected to the middle wire should make contact sooner or at the same time as the others, and break contact at the same time as or later than the others. Otherwise, if there is want of balance, the lamps may be burnt out.

We are glad to see that, providing that the fuse of a sub-circuit is sufficient to protect the smallest wire on the circuit, there need be no cut-out in the ceiling roses. These cut-outs have been a great nuisance in times past, and they are a danger with high voltage fittings, as a permanent arc may be started by one going. It has to our knowledge been very difficult to persuade fire insurance inspectors of the futility of these fuses.

There is one mistake, or, at least, an absurdity. In the rules for dynamos and motors it states that they should be protected from damp and dust, and should be so placed that no woodwork or inflammable material is within 12 inches from them horizontally or 4 feet measured vertically above them; also in the case of accumulators the same rules are said to apply. Now it is evident that accumulators and dynamos are rather different, and we have never seen a battery of accumulators which has not been on wooden stands, and we fail to see any danger in the practice. This point should certainly be altered at the earliest opportunity, as it mars an otherwise almost perfect set of rules.

A very easy and good rule which is given for the insulation resistance an installation should have is 10 megohms divided by the maximum number of ampères required.

We are pleased to see that systematic inspection and testing is urged strongly as a precaution against fire and annoying failure of the light.

In conclusion, we can recommend these rules as being fair and unbiassed, and capable of universal application by fire offices, architects and others. Restrictions are not placed upon any system or systems of wiring; the principles underlying the rules are scientific, and the results are reasonable, not dogmatic; and there is no doubt that a great benefit would be derived by their universal adoption and the suppression of some of the antiquated ones now in use.

Mr. Alfred Saxon Snell has been appointed by the Willesden Board of Guardians as architect for their proposed new workhouse, infirmary and cottage homes.

THE ENTASIS IN ITALY.

IN the *Architectural Record* (New York) for the present quarter Professor Goodyear pursues his investigation into the use of curves instead of right lines by Italian architects. His paper, entitled "A Discovery of the Entasis in Mediæval Italian Architecture," of which the first part is printed, contains a remarkable series of examples which are derived mainly from the cathedral of Pisa. Visitors to Italy will find it advantageous to be equipped with the Professor's articles, which are made more impressive by excellent reproductions of photographs which were prepared under his direction, and are therefore not to be confounded with those which are intended for the public in general. Professor Goodyear concludes by describing some examples of entasis found in buildings of a later date. He says:—

In these last paragraphs we have abandoned the treatment of the entasis in Mediæval piers in order not to omit new illustrations or corroborations offered by these pictures of points previously dwelt upon, all bearing on the general fact that subtleties of construction were systematically practised by the Italo-Byzantine builders. Additional cases of the Mediæval entasis will be described in a following paper. Meantime its general character may be further illustrated by a well-known Renaissance theatre, the Teatro Olimpico at Vicenza.

The Teatro Olimpico is a design by Palladio, constructed after his death. The stage scenery is a stationary construction of timber and stucco. Its central arch shows Palladio's use of the entasis in pilasters, a use which in this instance gives exactly the general results of the backward bend of the pilaster into the curve of the arch which appears in S. Miniato at Florence and in many other Mediæval piers. The same bend appears in S. Stefano, a Renaissance church of Vicenza, as a result of the use of the entasis in pilasters. And the Gothic cathedral of Vicenza offers a closely analogous and impregnable case of the corresponding Mediæval entasis. This is the church already mentioned as showing an entasis in half-columns which face chapel walls, instead of piers. These walls are solid, without even the break of a doorway, and are about 20 feet in depth.

It has been observed in the opening of this paper that Palladio's use of the entasis in pilasters is supposed by modern architects to be without a Roman precedent. A photograph from Baalbec shows, however, that the entasis was used in pilasters by the Roman architects of the second century of our era. I noticed this entasis at Baalbec in 1869, since which time the photograph now published has been in my possession. It is well known that many and important ruins of the city of Rome have disappeared since the sixteenth century. Two suppositions are therefore possible, either that Palladio did independently what the Roman art had done already, or that he was acquainted with Roman examples in Italy, similar to that at Baalbec, which have since disappeared.

In either case it is probable that we have at Baalbec an example of a Classic entasis which cannot be explained by theories of optical correction, and which must be due to æsthetic considerations. It is true that our instance is of corrupt style, but it is none the less important historically. None of the explanations of an optical illusion causing an apparent concavity of lines, to be corrected by an outward curve, will apply to such a case. The habit of considering the entasis of the Roman and Renaissance engaged columns as a wholly imitative feature, due to a cause existing in porticoes and not existing in the engaged columns themselves, may receive some shock from this example. As long as æsthetic considerations are allowed to have some share in the conception of the Greek entasis (also generally quoted for Egyptian obelisks) it would appear that they must have had a still more distinct influence in the engaged columns and pilasters of Palladio and of the Romans. Certain it is that the Palladian palaces of Vicenza are, of all Renaissance buildings, those which strike the student of optical refinement as having an effect of optical mystification analogous to that found in certain Mediæval buildings. Is it not possible that this is due to Palladio's universal and emphatic use of the entasis—his use of the curving line?

The point to be kept in view, however, is that, as a matter of fact, there are two sixteenth-century Renaissance examples at Vicenza of a peculiar bend of the piers supporting an arch, and that this bend is a counterpart and continuation of the Mediæval entasis of the pier.

This leads me to say that in the composition of this article I have been influenced to some extent by the very important letter below appended, and originally published in the *Evening Post* of May 3, which Professor Charles Eliot Norton was good enough to write me on the score of the discoveries which have been published in the *Architectural Record*.

Dear Mr. Goodyear,—I am much obliged to you for sending to me a copy of the last number of the *Architectural Record*. Your article in it is of great interest, and, in continuation of your former paper, it brings together a series of facts which cannot but change our con-

clusions in many respects in regard to the principles and methods of Mediæval building. You have opened a vast field for discussion, and you have provided a mass of material so exact and so well selected as to furnish a solid basis for the work of future inquirers.

But it seems to me that one result of your investigations is that much wider investigation must now be undertaken. Your work, while it solves many questions, has but opened many others. One of the most important, certainly one which it is very desirable to determine in order that we may understand properly the principles of Mediæval building, is whether the builders of the churches which show these remarkably designed irregularities erected them on a basis of well-recognised principle derived from authentic tradition, or whether in their construction they were using simply empirical methods handed down from generation to generation without intelligent understanding of their real significance.

If their work was based on a tradition from ancient times it is a surprising fact that we have no literary record of the principles by which they were guided, no reference, so far as I am aware, in any work later than Vitruvius indicating that the architects possessed a body of traditional principles by which the character of their work was determined. (And when was the tradition lost? How did the precious knowledge vanish from the minds of men?)

I am much obliged to you for bringing to my attention Mr. Middleton's article in the *Nineteenth Century*; it is a just but hardly a sufficient recognition of the value of your work, and it is of service as calling attention to the fact that there is now need of much more elaborate examination and careful measurement of the best Gothic structures in England, as well as on the Continent, than they have heretofore received.

I hope that it is your intention to gather up your own various articles upon the matter into a volume. It is not easy always to study a subject which is to be looked up in various numbers of various magazines. I hope also that your interest in the subject is such that you will carry on your investigations in other regions than Italy, for there is no one who understands so well as you the various points which are to be regarded, and the risks of overlooking some of the matters which require closest attention. Indeed, one of the most instructive general results of your investigations is the conclusion which one is forced to draw in respect to the fallibility of human perceptions, and the carelessness of our common observations of the objects which present themselves to our sight.

C. E. NORTON.

Prof. William H. Goodyear.

Two questions are raised by this letter which require consideration. How did the use of Mediæval optical refinements come to disappear, and why have we no record of them?

I suggest, on the first head, that they did not wholly or suddenly disappear with the close of the Middle Ages. The horizontal curves are found in the parapets of the Certosa at Pavia, which is Early (fifteenth century) Renaissance. The vertical curves appear in the Teatro Olimpico and in S. Stefano at Vicenza in a similar form to that which we find in the Gothic cathedral of Vicenza. It is well known that perspective illusions were practised by Bernini (Scala Regia) and by Borromini (Palazzo Spada). In fact, up to date such illusions have been only recognised as occurring in the Late Renaissance. The nave of St. Peter's narrows in 9 feet 4 inches between the entrance and the transept. This is quite possibly due to some special cause connected with the lengthening of the nave by Carlo Maderna, but it is not wholly impossible that an optical trick of the Bernini style is in question here. There is no doubt that a very considerable increase in perspective is obtained by this narrowing in of the nave at the third pier, and there is no doubt that this element of effect in increase of magnitude is universally overlooked. The deflected ground plans of the Middle Age are also paralleled in St. Peter's, whose nave axis is deflected about a foot from that of the choir. One is tempted to ask whether there have not been Masonic secrets which the Freemasons have neglected since they ceased to be masons. It may be that the secrecy of some of the Masonic guilds which preceded and developed into the modern secret society of the Freemasons may answer one of the questions which Professor Norton has raised as to the absence of written mention of the Mediæval refinements.

As to constructive asymmetry in the Renaissance, there is a suggestive passage in a recent German journal, apropos of the opening to the public of the Appartamento Borgia of the Vatican. I owe to the politeness of Mr. Edward R. Smith, curator of the Avery Library, my knowledge of this extract. The original German will be found in the *Kunst-Chronik* for May 15, 1897:—

Was it intention or was it necessity that none of the walls are parallel in any of the rooms of the palace of Nicholas V. or of the Torre Borgia? . . . All the apartments have the form of an irregular trapezoid. There are no right angles at the corners of the rooms. Consequently the division of the spaces of the vaultings (and their frescoes), and also of the walls, could not be managed without a certain haphazard (or arbitrary) appearance. Were the picturesque results reached consciously or unconsciously, by the abandonment of rules which no modern architect fails to consider? At all events, the Appartamento Borgia offers in this line also an abundance of material for thought and for study, and the influence which the arrangement and decoration of these magnificent rooms, now once more thrown open to the public, are destined to exercise on the palace architecture of modern times cannot be estimated.

Similar facts to those quoted may be noted in the Stanze of Raphael, and they are especially apparent in a more oblique setting and alignment of the pavement mosaic patterns than the irregularity of the walls would seem to call for. The given rooms are a construction of Bramante, just succeeding in time to those of the Appartamento Borgia. It is quite certain that one superiority of the early Renaissance architecture to the more formal and frigid later Renaissance style lies in its off-hand spontaneity and acceptance of natural irregularity. Possibly it also shows an occasional purposed avoidance of symmetry. There are very strong curves in plan in the loggie of the Vatican built by Bramante, which face the piazza. They are not due to movement of masonry, as they reappear in the inner wall of the third storey loggia. They may be due to carelessness, but it has not been usual to charge Bramante with this fault. Moreover, the inner wall curves and outer cornice curves are parallel.

Thus the survivals just quoted and others which may be brought to light, may illustrate a further gradual and natural dying out of the Mediæval refinements, which is already a very marked feature of the North Italian Gothic. Their ultimate entire disappearance would not be a startling fact in view of the tendencies to artistic blindness in our own age which the failure to notice the Greek entasis appears to specify and illustrate.

If the artistic effects obtained in many Mediæval buildings were due to a highly cultivated artistic sense, then the gradual dying out of this artistic sense, which seems to be a conceded result of nineteenth-century progress, would explain the disappearance of architectural refinements. If empirical observation of optical effect was one source of these refinements, the weakening of the modern eye will be one explanation as to why these effects are no longer studied. If traditional continuation of ancient classic methods was one source of the refinements, the gradual weakening of classic tradition through the later Middle Age will also explain their disappearance.

As to the absence of written records, which Professor Norton mentions, it is my impression that Mediæval writers did not indulge in architectural disquisitions or treatises on building. In so far as they have failed to give us systematic information on other points, it is not surprising that they should also have neglected this one. It appears in our own time that it is already growing difficult to write a connected history of the evolution of the steam-engine, owing to the disappearance of important early plans. Is it not a general rule that a vigorous and vital art does not tend to lay stress on literary record or literary elucidation? It would appear that the Greek works on the theory of architecture were later than the creation of the greatest monuments. In spite of the disappearance of these classic records, it is well known that many such existed, and that both optical corrections and optical illusions were considered by them. The preservation of Vitruvius was a lucky chance, and without it, it appears possible that the Greek curves might never have been discovered. We know that Pennethorne was prompted to look for the Parthenon curves by connecting his memory of those at Medinet Habou with the passage in Vitruvius prescribing the curves. These points are suggested with great deference to Professor Norton's superior knowledge of the matters concerned, and they may be summed up as follows:—The absence of literary mention during the Middle Ages may not be especially surprising, in view of the close bonds, professional jealousies and traditional secrecy of the Masonic guilds. The ultimate abandonment of optical refinements is preceded by an earlier dwindling away of the exceptional prominence which obtains for them in the eleventh century, especially in the Pisa Cathedral and St. Mark's. The Renaissance does show very late and very distinct survivals. Altogether, I think we shall be led by a study of this subject to a more vital apprehension of the overwhelming shipwreck which the Italian Renaissance brought upon Mediæval art—a shipwreck clearly prophesied in the Italian Gothic.

THE PARTHENON.

A CORRESPONDENT of the *Times* writes:—The Parthenon is doomed. These words are calculated to bring sorrow to the heart of every lover of Greece and Grecian culture. Perhaps many who have only seen the stately pile from below will be inclined to doubt the statement thus brusquely made. Indeed, when one sees the ruin from a distance or looks up at it from among the pillars of the western façade it seems so strongly built, so secure, that the visitor has no thought of decay and ruin, but leaves the place under the impression that the Parthenon will continue to defy time for countless ages. But the fact is that ever since the earthquakes of several years ago the immediate ruin of the Parthenon has been a foregone conclusion in case another earthquake should occur before certain repairs shall have been completed. As I write, in the spring of 1897, the whole western façade is

disfigured by an immense scaffolding, built in the strongest possible way from enormous beams that were brought all the way from America to serve Athens. This mighty scaffolding subserves a twofold purpose: primarily, it enables the architects to replace certain rotten and broken architrave blocks with fresh blocks; but its important secondary purpose is to serve as a prop to the entire entablature, and prevent the collapse of the building in case of an earthquake. I gained admittance to this scaffolding on two occasions recently. I was thus enabled to examine at close quarters the frieze of the western end, a privilege for which many have longed in vain. It is a privilege, too, that will not be reoffered to any one when the present scaffolding shall have been removed. From the base of the columns below any study of the frieze is out of the question—first, because, owing to the projecting epistyle, the bottom of the frieze cannot be seen, then because the whole frieze is distorted by the sharp perspective, and the lower-lying parts of the reliefs are hidden by the higher. The scaffolding affords, then, a unique opportunity for the study of certain chapters of Pheidias art.

But not to dwell upon the frieze longer in this connection, I must say that I was dismayed at what I saw. The inside and interior stones of the entablature are rotten throughout. In many cases these rotten stones were broken by the recent earthquakes into many pieces, though by the veriest miracle these pieces still cling together. As is well known the epistyle consists of three huge blocks that stand on their narrow edges side by side and span the intercolumniations. Of these three blocks the outside ones alone are comparatively sound, while the interior and inside blocks are in a most ruinous condition. All of these inside blocks are to be replaced by new ones that are now lying on the ground below ready to be hoisted into position as soon as the mighty derrick that is to lift them on high shall have arrived from Europe. The thought of new epistyle blocks in the Parthenon is shocking to most souls, and yet it is a choice between that and immediate ruin. The new blocks will be coloured with oil and wax in order to rob them of their glaring whiteness and newness. But even more sorrowful is the fact that, though this ruin may be stayed for one or two centuries yet to come, still in the end the Parthenon must collapse unless virtually the whole entablature be replaced by new and sound stones.

Am I asked for the reasons for this ruinous condition of the Parthenon? There are several reasons, several causes, some of which have been in effective operation for many years, though all unsuspected. We have been brought up to believe that the Parthenon was a perfect building erected by master builders, who employed only the best material in its construction. It occasions a shock to discover that though this is true in general, yet it is true with certain limiting qualifications, because of which the building is now threatened with ruin. In point of fact the builders of the Parthenon employed first-class marble only on the outside of the building, only where the eye could see it. In the Pentelic marble there are veins of schist that disfigure and ruin many a fair block. Visitors will remember the many unfluted drums of columns that lie here and there around the temple. These are drums that were rejected of the builders—rejected because they were faulty in some way, often precisely because of this disastrous vein of schist. Indeed, one of the new epistyle blocks has just been rejected by the committee of architects because of its faulty character, which was discovered only after the block had been completely hewn and was ready to be hoisted into position. No doubt that block will remain there for centuries to come, just as the rejected drums of columns have lain for these decades of centuries. Now, of course, perfectly sound marble was employed in columns, both because they were completely visible and also because they had a great weight to carry. Sound marble was employed also in the outside stones of the entablature and of the cella walls, but the inside stones of the cella walls, and the two inside stones of the epistyle were faulty from the start—faulty because of this vein of schist. As long as the building was covered by a roof the faulty character of these stones was of no importance whatever, and, as is well known, the Parthenon was always covered by a roof until its final disruption by the gunpowder explosion two centuries ago. The ruin that now threatens the portion left standing on that fatal occasion began from the moment of the explosion, and it has become more serious with each succeeding year. The roofless condition of the building has made it possible for the rain to penetrate into the schist-veins of the faulty stones. At first but slight damage was done to these stones, but the frost of winter and the scorching sun of summer made the evil greater from year to year, until at last the scales fall from our eyes, and we discover that these stones are rotten throughout. The horror was revealed in its full extent by the earthquakes, when a number of these rotten blocks were shivered into many pieces. The fact that these splintered blocks did not fall is due to the soundness of the neighbouring blocks on the outside. But though the ultimate cause of the ruinous condition of the Parthenon was the employment in its construction of poor marble for interior and

inside stones, which two centuries of exposure to rain, frost and heat have made rotten, still other things have conspired with these, namely, fire and cannon-balls before the disruption and earthquakes at all periods.

The repairs that are to be undertaken now are not to be thoroughgoing, but in fact are only temporary makeshifts, though they will perhaps preserve the building for a couple of centuries. Many will remember that twenty-five years ago the lintels of the grand doorway of the western end of the Parthenon were discovered to be rotten. In 1872 a supporting arch was built beneath these huge stone lintels. This arch rests upon the slabs of the Byzantine doorway. The present moment offers a good opportunity for replacing the broken lintels with new stone beams. Were this done, the arch and the ugly slabs of the Byzantine doorway could be removed, and then the mighty door would stand revealed in all its glory as it was conceived by Iktinos. It is known, too, that some of the stones used in this Byzantine patchdoor are inscribed. This fact is one more reason for removing the patchwork, because, to judge by the beauty and great size of the stones, the assumption that they bear valuable inscriptions does not seem to be an empty one. It is to be hoped, too, that the stairway to the Turkish minaret will be taken down. It has been left there up to the present because it supports rotten architraves; but we demand a purified Parthenon, and surely a few more new epistyle blocks would not disfigure the building one tithe as much as does this Turkish minaret. A conservative desire to remove only such of the old stones as are hopelessly rotten and broken prevails. This desire can be easily understood, and one's natural instinct is to share it; but, after all, sentiment should give place to common sense, which clearly calls for repairs more radical than those which are to be made.

And here comes in a fear for the frieze, the glorious frieze that fairly palpitates with the genius of Pheidias. When the final collapse of the Parthenon comes the frieze will be gone for ever. This remote danger, however, is not the only one that threatens the frieze; for there it stands exposed, like all the building, to slow but absolutely certain decay and ruin. In the recent earthquakes the head of one of the horsemen was broken off and dashed to pieces on the marble floor below. A similar fate is in store for the entire frieze, for the rotting process is already visible in the reliefs. In short, the reliefs ought to be removed now, so that they might be preserved in the museum for ages after the original entablature has ceased to exist. Dörpfeld did indeed propose to the committee that the frieze be removed to a safer and drier place and be replaced by a marble copy. But conservatism carried the day. The thought, too, that the removal of the frieze to the museum would seem to justify the spoliation of the shrine by the deeply-detested Lord Elgin had much to do with the stand taken by the majority of the committee. The frieze, therefore, will remain *in situ* and will perish.

There can be no doubt that the Parthenon would hold out for many centuries longer if it were covered by a roof. But it is thought by most men that a roof over the Parthenon would disfigure it absurdly. Of course it would, but then the roof would save the building, and sentiment would give the front seat to sound reasoning, which naturally would never, never do.

ROMAN ADMINISTRATION IN ENGLAND.

ALTHOUGH several hundred Roman inscriptions have been collected throughout the counties of England, and this number has been very considerably augmented by modern researches, it is remarkable how little light they throw upon the municipal organisation of the province. A single inscription exists to commemorate the sepulture of a decurion of the colony of Gloucester; while we have a hundred references to military there is no other whatever to any civil officer. It seems impossible to suppose that this can be merely accidental. Other countries teem with notices of *dumvirs*, *decurions*, *quinquennales*, *augustales* and *flamens*, but Britain is literally all but destitute of them. The solution seems to be forced upon us that the government of the Roman towns in Britain was generally purely military. Some light, perhaps, may be thrown upon this remarkable circumstance by another peculiarity in the Roman towns in Britain. All places of undoubted Roman origin among us were distinguished by the Saxons by the appellation of *Chester*, or *Castrum*; and these towns have a special type in common, to which, we believe, there is nothing similar in the Roman provinces on the Continent. They are all more or less square or oblong areas, intersected by two principal streets at right angles, such as we find to be the case at Colchester, Chester, Exeter, Chichester, Gloucester and, in fact, in every town among us which is reputed to stand upon Roman foundations. It is commonly supposed that all these places were originally legionary encampments, in which, after the reduction of the country, colonies were planted or civic establishments gradually grew up. Against this supposition,

however, the size of these enclosures seems strongly to militate. The walls of Chester are said to be two miles in circumference; those of Cirencester, as measured by Stukeley, a little more; those of Colchester about 3,200 yards; those of Exeter 3,000, and they generally range from 3,000 to 4,000 yards. Now, according to the measurements of General Roy, a camp of 1,000 yards by 600 yards would contain, on the Polybian scheme, 26,000 men, and on the Hyginian full 50,000; the first number would exceed two legions, and the second would not fall short of four. But the Polybian was the camp of Scipio; the changes introduced by Marius shook the discipline and morale of the legions, and it is far from probable that at least after the time of Julius Cæsar the soldiers could be induced to devote to the construction of their daily encampments the vast amount of labour required of them by the great captains of the republic. Hyginus details the practice of the time of Trajan, when the same extent of earthwork was made to hold twice as many men as at the earlier epoch; but this was only thirty years after Nero, and we see no reason to suppose any great change had taken place in that brief interval. If we were to press this argument, therefore, it would show that the supposed camps of Colchester and Cirencester and Chester were constructed for armies of 50,000 or 60,000 men. But it is doubtful whether there were ever more than four legions in Britain together, at least before the time of Severus, whose armies, according to Dion, were very numerous, and in the highest degree improbable that such a force was ever collected at the same time in one place. If, on the other hand, it be asserted that these enclosures were constructed not for temporary but for static camps, that is, for the permanent maintenance of a Roman garrison, we may point to the places which are known to have been established with this view—the stations of Caistor, near Norwich, of Burgh Castle, Richborough, Reculver and Lymne, and show that these places are each not more than 200 or 300 yards square.

MARINE SALT IN PLASTER.

ONE of the causes of the decay of the frescoes in the Houses of Parliament is supposed to arise from the use of plaster which was prepared from limestone from Durdham Down, near Bristol. All the beds of Durdham Down limestone are of marine origin, being full of marine shells; and, although in the long lapse of ages since they were deposited, the marine salt, with which the stone must have been saturated, has, for the most part, been washed out, yet still a trace of it remains, insensible to an ordinary analysis. It is the general practice to burn this stone into lime with braize (or cinder taken from the scavenger's yard), and this braize always contains sulphur. In burning the minute quantity of marine salt in the stone is converted, for the most part, into sulphate of soda, or the salt well-known in commerce as "Glauber salt." On most of the walls that grow cold in winter needle-form crystals are found, varying from a bloom 1-100th of an inch to needles of an inch in length, and in some instances, in damp old walls, such as the cloister walls of a cathedral, the crystals stand out to the length of 1½ inch. They are generally composed of sulphate of soda, in rare instances mixed with nitrate of potash, and sometimes with small quantities of muriate of lime and magnesia. When the weather becomes dry all these bunches of crystal effloresce, and are converted into a loose white powder, much of which drops from the wall, carrying with it shales of plaster, or flakes of paint, or films of whatever material the surface of the wall is covered with. Moisture will condense on the wall if allowed to grow cold in damp weather; the white powder is then dissolved, and the liquor, a solution of sulphate of soda, is absorbed by the mortar or plaster. Architects are in the habit of proving the value of the various kinds of stone presented for their use, for the endurance of frost, by a saturated solution of sulphate of soda, similar to this liquor, which on crystallising imitates the heaving and splitting action of ice forming from water. Accordingly, this liquor is no sooner absorbed as the wall dries than it aggregates into ice-like crystals, and the plaster is disintegrated and heaved by the dynamical force developed in their formation. The plaster having sustained this injury, the salt transforms itself, and shoots out into bunches of needle-form crystals, only to fall again into the terrible white powder, as the air becomes warm and dry. Thus a constant succession goes on of solution and desiccation, with the changes of the weather and temperature; and if the wall be permitted to cool with the frost, the ruin of the plaster is insured. Sulphate of soda exists not only in Durdham Down limestone, but unfortunately also in much abundance in all the *lias* mortars, in London clays, and in many other stones. In fact, it may be doubted if any London wall is free from its presence. We may, therefore, observe this kind of action of destruction going on more or less almost everywhere. In Rome and Florence, indeed, many frescoes have remained entire, with their colours smooth and in good order, for hundreds of years.

NOTES AND COMMENTS.

THE demands on the French Exchequer are too heavy to allow of grants for the restoration of many of the public buildings. M. BERGER has therefore proposed that the Government should dispose of a part of the land which is occupied by the fortifications of Paris. Two months ago it was admitted by the War Minister that as much of the fortifications as extend from the river along the Bois de Boulogne do not add to the security of Paris. On the other hand, the lines are obstacles to the extension of Paris. It would therefore become an advantage to many if the land occupied by the fortifications were sold, but there are other Departments of the State coveting the proceeds. At one time an effort was made to secure the money for the construction of warships, and there would be little difficulty in applying it to advance Russian interests. In whatever way the money is disposed of, there is no doubt the fortifications in question will have to make way for new streets lined with lofty buildings.

ON last Palm Sunday the cupola of a church in Brousse, in the department of Tarn, fell during service; seven of the worshippers were killed and about thirteen were wounded. On Saturday last MM. BONNET & CROUZET, architects, with MM. PELISSIER & MIQUEL, contractors, appeared before the Tribunal Correctionnel at Havre, being accused of "homicide par imprudence" in connection with the catastrophe. The church was constructed in 1867, and it exemplified the showy and insecure but cheap style which is now too common in the French provinces. The vault apparently was only a sort of shell or basin lying on the walls, without any groining or security against expansion. During last winter the rain attacked it in two ways, first by entering through the courses, and secondly by causing the walls to settle. The large congregation was also declared to be one of the factors in the collapse, for the people were not uniformly spread over the floor, and as it sank the walls became unstable. The original architect, M. RIVET, died some years ago, before the church was complete, and the responsibility was therefore cast on MM. CROUZET & BONNET, who succeeded him. They were also accused of having erected a belfry which was too heavy for the foundations. The architects claimed the benefit of the prescription in the Code Napoléon (2270), by which after ten years architects and contractors are discharged from guaranteeing the works they have made or directed. The Tribunal allowed them to go free; M. PELISSIER, the contractor, who declared that he followed faithfully the architect's plans, was also exempted; but before arriving at a decision an inquiry was ordered into the share taken by his partner in the construction of the building.

THE death of the Duc d'AUMALE has not interrupted the restoring of the picturesque Château d'Amboise on the Loire, which he had purchased from the representatives of the Comte de PARIS. The Duc's idea was to use a part of the building as an asylum for old servants of the ORLEANS family. Accordingly, he founded a society in order to evade any difficulty which might be raised by a Republican Government against such an appropriation of an historic building. He supplied sufficient money to pay for the works of restoration, and had plans prepared for the new arrangements. The part of the building overlooking the Loire is to be used as a museum. The alterations will be completed in 1899.

THE highest appointment open to an architect in the United States is that of supervising architect to the Treasury. Judging by the experience of past years, the tenure of the office is very brief. Probably with the intention of gaining an architect who is able to sustain the attacks on his conduct, which are inevitable however able or impartial he may be, it is now proposed to apply the competitive system to candidates. The salary is only about 900*l.* a year, but it is expected that a gentleman of high attainments and administrative ability will be secured. The candidates are to fill up forms giving information about their training and technical experience. They are also to submit drawings or sketch-plans, specifications and photographs, or other illustrations, of buildings

designed by them as architects, or constructed under their supervision; and two essays, one relative to designing and construction, and the other relative to office administration. The candidates must appear, on September 10, at points convenient to their places of residence, where the Civil Service Commission has suitable accommodation, for examination in regard to their qualifications for preparing a scheme for competition for a public building, and for criticising designs submitted to them for their inspection. The examination papers will be considered under the direction of the Commission by a board of architects of distinction.

HOLIDAYS are not allowed to interrupt the business of the Architectural Association for long. As a warning to all members against surrendering themselves to pleasure, the curriculum for the session 1897-98 has appeared. Not only are the classes arranged for every day, but the general meetings as well. The programme is mainly made up of practical subjects which are especially adapted for the younger members of the Association. The following papers are to be read during the session:—"Practical Lessons from the Paris Bazaar Fire," by Mr. EDWIN O. SACHS; "Classification of Trades," by Mr. S. FLINT CLARKSON; "Some New Materials for Use in Building," by Mr. H. D. SEARLES-WOOD; "The Planning of High Schools and Endowed Schools for Girls," by Mr. J. OSBORNE SMITH; "House Painting," by Mr. L. A. SHUFFREY; "Composition in regard to Public Buildings," by Mr. F. T. BAGGALLAY; "Hampton Court Palace," by Mr. JOHN BELCHER; "Leadwork, Plain and Decorative," by Mr. F. W. TROUP; "Scottish Ecclesiastical Architecture in the Fourteenth and Fifteenth Centuries," by Mr. HIPPOLYTE J. BLANC; "Constructional Steelwork," by Mr. T. C. CUNNINGTON; "The Morality and Economy of Competitions," by Mr. H. B. CRESSWELL; "Interior Lighting (Reflected Lights)," by Mr. W. ECKSTEIN; "Electric Lighting as applied to Architecture," by Mr. TOM ELKIN; "Foundations as applied to London Buildings and Riverside Foundations," by Mr. A. T. WALMISLEY.

WHENEVER several room-keepers and other occupants of a poor class are to be evicted in consequence of the proposed erection of large buildings, there is an outcry about the inhumanity of builders. In most cases it is now necessary to show that ample provision for accommodating the people is available. In a short time there will be a clearance at Westminster in order to obtain possession of the buildings which have to make way for the new Government Offices, but as yet the philanthropists make no sign of displaying any of their exuberant sympathy with the sufferers. Where there are leases the Office of Works cannot ignore them, and some sort of compensation will have to be paid to the holders. But there are few occupants who possess that sort of security. The majority of the men who occupy rooms in Parliament Street and the neighbourhood are yearly tenants, and, indeed, the tenure of many is for a shorter term. That fact has not prevented them from living there for several years. The occupants, too, form an important body. Among them are designers of engineering structures, surveyors, draughtsmen, calculators, chemists, financial agents, assistants to the parliamentary agents, &c.—in other words, the rank-and-file of the corps who have constructed great works in England according to the regulations of Parliament, and who are connected with similar works in other countries. It is not to be supposed that the occupants are richer than men in other callings who have to "devil" for their employment is precarious, and the credit of their best work is taken by those who pay for it on moderate rates. But they are compelled to live near the successful engineers, lawyers and parliamentary agents, and it is no less important for them to be able to appear in a parliamentary committee-room at a moment's notice. By turning these men out of their rooms in Westminster, especially at a time when the private bill work of the coming session is under consideration, is to cause serious inconvenience, for it is not easy to find accommodation in Westminster; but what increases the grievance is that not a penny in compensation will be paid by the Government to any occupant who is not a leaseholder, although he may have held his room or rooms for half a century.

CATHEDRAL SERIES.—CANTERBURY: BECKET'S CROWN FROM TRINITY CHAPEL.

IN an architectural sense there is no part of Canterbury Cathedral more interesting than the Trinity Chapel and Corona, because in that part of the building the skill of the English WILLIAM is more apparent than elsewhere. It has besides associations with the martyred Archbishop. GERVASE, in describing the building in which the murder was perpetrated, speaks of a chapel of the Holy Trinity. He says that there "the blessed martyr THOMAS celebrated his first Mass on the day of his consecration, and in this chapel before, and after his exile he was wont to celebrate Mass, to hear service, and frequently to pray." Although it is supposed that the Archbishop, when the knights appeared, wished to make his way to the high altar in order to meet his death, yet it is not unlikely that the goal which was in his thoughts was the chapel which was dear to him. When the rebuilding of the cathedral was commenced four years after the murder, the present Trinity Chapel formed part of the plan, and more architectural importance was conferred on it. Presumably the chapel was intended to hold BECKET'S shrine, although the evidence on that point is not convincing.

To the majority of visitors Trinity Chapel and the Corona appear to be uniform with the choir, and are assumed to be the work of one architect. But the Mediævalist architects always were eager to assert their individuality, and WILLIAM the Englishman would not be considered disloyal to his master, WILLIAM of Sens, if he introduced a few variations. On this subject Professor WILLIS writes:—

It is a very difficult task to separate the original work of William the Englishman from that of his predecessor. Gervase, indeed, has told us pretty exactly all that was erected during his superintendence, but much of this must have formed part of the original design of William of Sens. The erection of the new Trinity Chapel, or chapel of Becket, which took place wholly under the direction of the Englishman, must have been intended from the beginning, for the contrivance of narrowing the central alley of the choir, for the double purpose of avoiding the old towers and of adjusting the width to agree with that of the ancient chapel of the Trinity, was due to the French artist, seeing that the inclined part of the choir was carried up to the clerestory before his fall. Whether we are to attribute to him the lofty elevation of the pavement of the new chapel, by which also so handsome a crypt is obtained below, must remain doubtful. The bases of his columns, as well as those of the shafts against the wall, are hidden and smothered by the platform at the top of these steps and by the side steps that lead to Becket's Chapel. This looks like an evidence of a change of plan, and induces me to believe that the lofty crypt below may be considered as the unfettered composition of the English architect. Its style and its details are wholly different from those of William of Sens.

The Trinity Chapel of the Englishman is under the influence of the French work, of which it is a continuation, and accordingly the same mouldings are employed throughout, and the triforium and clerestory are continued at the same level; but the greater elevation of the pavement wholly alters the proportion of the piers to their arches, and gives a new and original and at the same time a very elegant character to this part of the church compared with the work of the Frenchman, of which at first sight it seems to be a mere continuation.

The triforium also of this Trinity Chapel differs from that of the choir in that its four pointed arches, instead of being like them included under two circular ones, are set in the form of an arcade of four arches, of two orders of mouldings each. The mouldings are the same as in the choir, but the effect of their arrangement is richer. Also in the clerestory two windows are placed over each pier arch instead of the single window of the choir. The mixture of the two forms of arches is still carried on, for although the semicircular arch is banished from the triforium it is adopted for the pier arches, as shown in the section. However, in the side aisles of the Trinity Chapel and in the Corona our English William appears to have freed himself almost as completely from the shackles of imitation as was possible. In the side aisles the mouldings of the ribs still remain the same, but their management in connection with the side walls, and the combination of their slender shafts with those of the twin lancet windows, here for the first time introduced into the building, is very happy. Slender shafts of marble are employed in profusion by William of Sens, and Gervase expressly includes them in his list of characteristic novelties. But here we find them either detached from the piers or combined with them in such a manner as to give a much greater lightness and elegance and effect than in the work of the previous architect. This lightness of style is

carried still further in the Corona, where the slender shafts are carried round the walls and made principal support of the pier arches, over which is placed a light triforium and a clerestory, and it must be remarked that all the arches in this part of the building are of a single order of moulding, instead of two orders as in the pier arches and triforium of the choir. The square abacus, however, is used throughout.

ART IN THE DEPARTMENTAL SCHOOLS.

THE following extracts from the reports of the examiners will suggest the general character of the work produced in 1896 in the schools of the Department of Science and Art:—

Freehand Drawing of Ornament.

The work in both stages of this subject seems to be quite up to the average of last year, the larger part, as usual, being of mediocre value, but there is certainly a marked decrease in very bad drawings.

Many candidates whose drawings are well balanced and neatly lined in, but quite unlike the copy, give evidence of their mistaken idea that a clean wire line is the chief thing to aim at, and their anxiety to produce this has caused them to miss the larger and more essential qualities of general planning with shapes of spaces between the ornament.

Geometrical Drawing (Art).

A good proportion of the candidates showed very creditable powers of draughtsmanship, some papers indeed being quite admirably worked; but still in far too many cases it seems hardly to be understood that the examination is in drawing as well as in knowledge of geometrical constructions. Many marks are lost through the use of unsuitable pencils (which candidates appear unable or unwilling to sharpen) and of very inferior instruments. It should be borne in mind that careless and clumsy work is of little or no practical value.

Model Drawing.

Elementary Stage.—It is gratifying to note that more care has been given to the teaching of this stage of model drawing, resulting in the attainment of a still higher level.

Fewer incomplete drawings were submitted for examination, and the perspective knowledge displayed is satisfactory, but the relative proportion of the four objects leaves much still to be desired, indicating that many schools have not supplied themselves with models in accordance with the syllabus for model drawing issued by the Department.

Advanced Stage.—It is very apparent that a large number of the candidates in this stage do not give sufficient attention to the shading of the group; this may in a measure be accounted for by the fact that shading must necessarily come last.

In this stage a considerable advance is attained in the perspective rendering of the groups. The drawing is more accurate in the cones, pyramids and prisms, the principal failures occurring in the skeleton cubes and vases.

Drawing in Light and Shade from a Cast.

The examiners notice with pleasure a marked improvement in the candidates' work, especially in the advanced stage.

The work, as compared with last year, seems more intelligent and thorough.

Good proportion was rarely met with, especially in the elementary stage; the proportion of the height to width of the cast was most frequently incorrect and often very much out, even where the expression of light and shade was fairly good.

Perspective.

Whilst the number of candidates presenting themselves for examination is still decreasing, the work done is of decidedly higher merit.

Design (Elementary and Advanced Stages).

The works sent up in the elementary stage are, on the whole, satisfactory; absolutely incompetent work grows year by year less, and (with few exceptions) conditions begin to be much more carefully observed. In one respect at least there is very marked improvement in the way of executing designs; they are much more generally in water-colour, which is the medium specified. Improvement is also to be observed in the design of ornament, which is, generally speaking, more logical than it once was. It is now only by exception that a scroll is made to grow in two opposite directions, at both ends, that is to say, or that a flower is provided with two separate stalks.

The work sent up in the advanced stage is relatively not so satisfactory as that in the elementary stage. There is some very good work in the exercises which gain, say, half the

maximum number of marks, but after that there comes a sudden falling off in accomplishment. It should be stated, however, that here, as in the elementary stage, and perhaps more markedly still, there is a great improvement in the logical consistency of pattern-growth.

Material and Process.—Candidates were asked to state in writing the material and method of execution proposed in their design. Occasionally they make no such statement, sometimes they make only one of these statements, frequently they write something haphazard quite contrary to what the drawing indicates, if it indicate any material or process at all. It is quite clear that in very many instances the design was first made, and then the student began to think what it was fit for; and it has puzzled him to say. This is not as it should be; and it is disappointing to find at this stage so little appreciation on the student's part of anything like workmanlike design. In designs for painted decoration there is no great appreciation shown of what constitutes decorative treatment. A fair understanding of what is meant by "modelled relief" is more general, although designs described as for modelling are in some instances more obviously suitable for painting.

Candidates were not asked to design in any given style, nor even in any existing style at all, but merely to design as though their work were to go with a room or building of some definite architectural character. That is a condition under which the greater part of design is, and must be, undertaken; and it is of the highest importance that the student should be able to work under it. This examination shows how little he can do that.

In reference to the written statements as to material, method, style, &c., candidates not only give too little information, but too much; they attempt to describe a process in detail when all they are asked to do is to state the method of execution. The demand for that short statement has too often brought down upon us a flood of explanation which explains nothing. The examiners do not want any process explained to them, but only to be sure that the student has a distinct idea as to the process by which his work is to be executed, and that he can make a practical design for that process.

Students do not clearly enough realise that what the examiners want to see is what they can do, and how well they can do it. When time is limited, as in these examinations it must inevitably be, one condition of success is not to waste it. The examiners wish to point out that, though in the matter of accuracy of measurement and observance of conditions there is still great need of improvement, things are in these respects distinctly better than they were; there is hope in that.

Some of the designs sent up this year in both elementary and advanced sections are excellent, and many of them are creditable to students and masters alike. Appreciation is expressed by the marks awarded, but it is thought more helpful to point out where students have gone wrong than to dilate upon excellences about which there is really nothing to say but that they are excellent.

Design (Honours).

It gives the examiners pleasure to report that in the papers of the present year there are some admirable designs, and though compared with the large number of competitors these finest examples may appear proportionately few, it must not be forgotten that the best powers of figure-design demanded in Design (Honours) are exceedingly rare. Among hundreds of students it is much to find one so endowed, and that one might remain unfound and undeveloped except for such incentive as this competition and its preparatory training supplies.

All these works are also composed without knowledge or foresight of what subjects will be set the students when assembled. It is also pleasant to note that the number of designs "characterised by swinging unmeaning swirling lines about," which was condemned in last year's report, is this year very reduced.

The suggestion that charcoal should be disused in this subject has been almost wholly complied with, with the satisfactory result that there is very little of the dirty groping and haphazard fooling and smudging which was before deplored. Almost all the papers show increased and more resolute endeavours after clear and defined execution. And when one reflects how much of the year's matter must come from comparatively new and raw students who have never entered the lists of Subject 23*d* before, there is much ground for encouragement, notwithstanding that it is again necessary to remark that not a few of the competitors are of so low a standard that they ought not to have been permitted to enter. All students who desire to compete in this subject should be proved beforehand by calling on them to give evidence of some capacity of design within a few hours' work. This would considerably thin the ranks with advantage to all.

But the prevalent impression is the rarity of the sense of beauty; perhaps in this age of ugly conditions surrounding it must needs be so. But masters might do much to cultivate susceptibility to grace of form among their pupils by setting ugliness and beauty, deformity and proportion, in strong and

frequent contrast before them, encouraging them to search into and define the features that differentiate the one from the other.

Anatomy.

The examiners are pleased to report a much higher standard of excellence this year than has existed for some time previously. Nineteen candidates have distinguished themselves by papers of great merit. In all the nineteen papers the drawing is such as to indicate that the candidates are fully aware of the significance of the details of which they are such masters. The examiners do not remember for some years past to have met with papers of such excellence in which the candidates displayed so thorough and practical a grasp of their subject.

As usual, a large number of the rejected candidates have apparently entered for the examination with little or no preparation, and an entire lack of appreciation of the relation of anatomy to their other studies. The number of such candidates is smaller than in 1895, and, as a whole, the standard of the examination this year is higher than the average.

Architecture.

The number of candidates' papers this year amounted to 486, showing an increase of 37 as compared with 449, the number in 1895.

The quality and character of the work is, generally speaking, fairly similar to that of the past and recent years, but the advanced students have not done quite so well, and the average students have done a little better than last year. The work of those who have failed is in the main very much as before, but it should be added that some of the worst is extremely bad this year. On the other hand, it is gratifying to be able to say that some defects, which had been conspicuous even in good work, have become sensibly more rare.

The questions as to Renaissance architecture have been less frequently attempted than any others, a circumstance which is regretted. The questions requiring buildings or parts of them to be drawn from memory have elicited a great many answers, of which the larger proportion have been satisfactory, in some cases very much so. Fewer attempts in bad perspective have been made in answer to these questions than last year, though still some students have attempted to show buildings or parts of them in perspective without achieving even moderate success. It is, however, satisfactory to add that some perspective studies of portions of buildings have been submitted of very great merit, the best undoubtedly being those where single features, such as a doorway or an arcade, have been the subject. It is also gratifying, in answer to a question calling for a written description of a building, to receive in a few cases an account of an English church or cathedral; this is a welcome change from descriptions of the Parthenon or the Pantheon, which are simply quoted very nearly word for word from a handbook. The power of giving an account of a building in writing is a very useful one, and describing even a very simple building with which the student is familiar is a much better proof that he possesses such a power than the reproduction of some other person's account of a building which the student himself has never seen. In the answers to a question on the meaning of architectural terms, a question which has been attempted by the great majority of candidates, more accuracy and better information was shown than in dealing with a similar question last year.

Architectural Design.

The subject set was the chance of a large and important church. A slight outline sketch was issued to candidates to give a general approximate idea of the size and height of the proposed chancel, but beyond this candidates were left entirely free, both as to their treatment of the subject and their choice of style. In examining the designs no questions of ecclesiology or ritual were taken into account, but marks were awarded solely on the merit of the work as architectural design.

Out of the seventy-two candidates fifty-three, including nearly all the most successful, have selected some phase of Gothic architecture. Many of them were evidently attracted by the possibilities of the subject to attempt something grandiose and elaborate, and the general result has been that, along with many failures produced by candidates who probably would have failed whatever the subject set, this problem has elicited a much larger amount of creditable work than has been looked over in connection with this examination, not only in last year but in several past years. It has been gratifying to find that many art students have such a good acquaintance with Pointed architecture as the best of these designs display.

With regard to the candidates who have only gained very low marks there is not much to be said, except that as yet they know too little of architecture to be able to attempt to design a building with the smallest prospect of success. But some who have advanced beyond this stage, and yet have failed to pass, appear to show a want of familiarity with architecture as it exists in buildings.

Students who have advanced some little way in the study of Gothic architecture can best fit themselves for learning to design by sketching and measuring good existing examples. In closing, it is regretted that when a subject is set which has so often and with so much success been treated in some Renaissance style, there is only one Renaissance design in the rather long list of the works that stand out from the general body of designs.

Principles of Ornament.

Great care seems to have been taken by the masters in instructing their pupils in the principle of ornament, and the result is a high average, but scarcely any of the candidates show exceptional brilliance, and there is a marked scarcity in the papers in which the human form is represented. The teaching seems generally to be good, although there are some metaphysical definitions given of symmetry and balance which are not very clear. The papers as a whole are satisfactory, and a large number are extremely creditable, though it seems there are signs here and there of cramming, and by this is meant that students are practised in drawing illustrations to the questions likely to be set, which are drawn much better than the rest.

Painting from Still Life.

The examiners are pleased to report that the standard of the work in this exercise continues to rise, and throughout the whole of it, with only a few exceptions, there is evidence of the good results of sound teaching. They are likewise pleased to note an entire absence of examples such as those which on former occasions they stigmatised as disgraceful.

Painting Ornament in Monochrome.

Generally the work compares favourably with what has been done before, and in particular it is more workmanlike. Conditions are also on the whole more strictly observed than heretofore. Those who (again this year) cannot see that the diagram is not a square but tall in proportion to its width, and who distort the drawing in consequence of trying to fit the tall design into the wide space, lose marks. Comparatively few candidates have taken liberties with the design, and none of those who have are very successful.

It should be observed that though some liberty of treatment is allowed it is not desired. Least of all should it be taken as an opportunity of shirking the difficulty of the subject. Some renderings which are little more than outline drawings are obviously not the exercise set. They afford little test of painting, and consequently do not get high marks. The result of slackening the rule as to "grisaille" and allowing "monochrome" has been on the whole successful. A certain amount of crude colour occurs, but speaking generally, the colour is fairly tasteful. The weaker students fall back for the most part upon merely dull and dirty tints.

In some of the more confidently painted works the manner is rather aggressive. Direct work is what is wanted, but not brutality, which it sometimes amounts to. The broad surface of the shield in the diagram offered an opportunity of painting which few have seized. The lettering has troubled students more than it should have done. Many give no lettering at all. Many have just sketched it in. Some have done just enough to show how badly they would have done it.

There is a rise in the number of fairly clean and workmanlike exercises. There is distinctly less slapdash, over-confident work, and, one is happy to say, very little of the pretentiousness of quite incompetent candidates, which used frequently to be seen. That is to say, many of the works marked similarly to last year are better painted than the samples of last year's work thus marked. This indicates improvement.

Drawing from the Antique.

The average of merit in this exercise is in the opinion of the examiners decidedly good, and superior to that of former years. The execution in almost all cases is suitable to time-work, with the exception of a few drawings which are still blackened all over from senseless overshadowing.

Drawing from the Life.

In spite of the considerable increase this year in the number of works, the examiners find no falling off in the majority of them, and are much pleased with the intelligence shown in most of them. The proportion of bad drawings is diminishing, though there are still a few outrageous drawings remaining that can only disgrace the schools they come from.

Drawing the Antique from Memory.

Most of the drawings in this extremely useful exercise are very satisfactory, the average qualities being decidedly higher than in previous years. The examiners are pleased to see that the student has derived much benefit from the study of the antique, and retained in his memory a feeling for the proportion and movement of the statue, and is able to transfer to paper

in a suitable and intelligent manner the knowledge he has gained.

Historic Ornament.

The papers in the examination for historic ornament show an unusually good average of awarded marks. There is not a single paper returned blank, and few which do not give answers to six or seven of the eight answers permitted. The sketching of objects of various kinds in illustration of the candidate's meaning shows a marked improvement.

Modelling Design.

Elementary Stage.—In this stage (apart from a few which are quite excellent, and a number of others which are very good) the work generally is exceedingly poor, a good deal being not properly modelling at all, but mere shapes scratched out, expressing no more than bad outlines would. It should be observed in this subject that, however low the relief may be, there should be some degree of intelligent and expressive modelling. Otherwise there is no reason for its being done in clay, as an outline drawing would express quite as much. There is a tendency to too great profusion of ornament, many of the designs being an absurd crowding of ugly bad ornament. It may be pointed out that it is a very high merit to make a good design at the smallest possible expense of ornament, quality rather than quantity being the aim.

In most cases the usual conventional ornamental forms are adhered to. In a number of instances, however, natural flower forms are used, but in few cases with any degree of success. This is unfortunate, because the adaptation of natural foliage to ornament is most commendable, and gives every chance of developing the student's originality.

There are some works which show considerable skill and care in the manipulation, evidently the result of the trade the students are engaged in (probably that of chasers in metal), but which show an almost total absence of design, *i.e.* taste or reason in the application of the ornament or appropriateness to the shape of the panel.

Advanced Stage.—The work in this stage reaches a very high average indeed. It is most gratifying to see so very many altogether excellent designs, the great number that are quite good, and the high average quality of most of the others. The really poor in this stage is a comparatively small proportion. It is especially gratifying to see the large amount of originality and individuality combined with good taste, without which, indeed, originality is worthless. There is one great weakness, however, to which attention must be called. This is the extremely bad lettering in a very large proportion of the door-plate designs. The presence of bad lettering in designs, which are in other respects refined in taste, shows that this is because lettering has not been studied, and not because the taste is bad. The necessity of studying lettering cannot be too strongly urged. Good alphabets should be at hand in all schools. It is most sincerely to be hoped that teachers will give some attention to this most fruitful element of interest in ornamental design. The appreciation of treatment for material intended is most satisfactory.

Modelling Design (Honours).

Although there are fewer works this year, the standard of excellence is far below that attained last year. There are a few works which show some promise, but there is not a single specimen well modelled, and most of the examples appear to be the work of beginners, many of whom may some day become well skilled in their art, but at present are certainly not qualified to sit for the above examination. It must again be urged that all work of an elementary nature is incompatible with the objects of this examination. It gave no pleasure to examine this collection, and it is regretted that a more favourable report cannot be given.

Modelling from the Antique.

Although there is again a large increase in the number of works submitted, it is gratifying to see there is no falling away from the improvement manifest last year. Indeed, judging the works as a whole, a higher standard has been attained this year. This satisfactory result is in a large measure due, it is believed, to the increased effort which has been made by the candidates to represent correctly the structure and character of the example set before them. The importance of great care in this direction cannot be too often or too strongly impressed upon the students.

Modelling from the Life.

A large proportion of the works sent up are poor to a degree, showing that many of the candidates had been insufficiently prepared for this exercise, and they should not have been allowed to sit. The opinion expressed upon the work last year, as to the advisability of students not being permitted to model figures from life until they were able to draw with some degree of accuracy, applies with equal force to the works submitted this year.

SOMERSETSHIRE ARCHÆOLOGICAL SOCIETY.

(Concluded from last week.)

SECOND DAY.

THE second day of the meeting of the Somerset archæologists was devoted by the members of the Society to excursions westward of Bridgwater, about 140 of them leaving the Cornhill punctually at 9.30.

The parish of Stogursey was first visited, and on the party alighting here they first proceeded to the parish church, which Mr. Buckle, the honorary diocesan architect, described as a splendid example of early Norman work, the tower especially being a very fine example of it. The width of the four central arches clearly implied that the nave must always have been as wide as it is now. In many cases where they had a Norman central tower the nave was very small indeed, making it almost impossible to see the chancel; in this case, however, it was exactly the contrary. After referring somewhat in detail to the size and shape of the arches, he expressed an opinion that the Norman window on the south side of the chancel was moved at the time of the restoration and not replaced in its true position. When the restoration took place the east wall was entirely taken down and rebuilt, and that consequently was all modern. Practically all the windows were of the earlier Norman period. He pointed out one or two peculiarities with regard to the rood door, on the side of the pulpit, below which there was an archway, but whether it was originally intended that that should lead to the small chapel behind or not he could not say. At the present time there was a square block of buildings containing a staircase reaching to the tower behind the archway, but whether there had been any alteration there in comparatively recent times he was unable to say. There was a good deal of carving on the bench ends, principally of the sixteenth century, the majority of which was of a Flemish character. Spires were very rare in West Somerset, and this one was a small wooden building covered with zinc inserted at the top of the tower. In conclusion, Mr. Buckle directed attention to a monument erected to the memory of Sir James Burnett under one of the arcades of the chancel.

The Rev. F. Meade-King added a few words, after which many of those present adjourned to the vestry and inspected several old registers and some communion plate.

The site of Stoke Courcy Castle was next visited, and Mr. Buckle being invited to say a few words with regard to it, that gentleman observed that practically he knew nothing of the castle, but it was recorded to have been fortified by one Falke de Brent in the time of Henry III., and to have been destroyed by Lord Bonville in the time of Henry VI. The castle itself, as they could see, consisted of practically but a moat and a circular wall, and he doubted if ever it was a habitable dwelling. There was nothing left, at any rate, of a domestic building if any had ever been in existence. If it had been used as a dwelling-house when they had a number of troops there it must have been a very uncomfortable one indeed.

Dodington Manor was next visited, and briefly described by Mr. Buckle, who said the chief feature of the interior was the hall, which was a remarkably perfect one. The roof was very interesting, as it varied to some extent from the ordinary pattern of a hall roof of the fifteenth century. There was a tendency for all the beams to be very wavy, and he attributed this to the fact that the tree the four principal beams were made of was peculiarly shaped, and that the carpenter used it as being the only wood he had. It was evident, however, in respect of some other beams that the carpenter had wilfully made them wavy. The windows of the hall were apparently a good deal later than the building itself, and were probably of Elizabethan date. The mantelpiece, dated 1581, was a very elaborate piece of stonework, but work of the crudest possible class, and was evidently done by some un instructed country mason. He commented especially on the wretched figures at each end, and of one in particular, which was apparently intended for a horse. It may be added that below the figure referred to was the Dodington crest, bearing the words "Support thy patrimony," and the date 1581.

From Dodington the party were next driven as near as possible to the site of Stowey Castle. Many of the members, including several ladies, ascended the rather steep declivity leading to the mounds on which the castle stood, and here the Rev. W. Greswell read a deeply interesting paper, in which he remarked that the position of Stowey Castle in former days must have been a strong one—naturally far stronger than the site of Stoke Courcy Castle. The Rev. F. Warre considered that this mound was one of a line of British earthworks, and he ranked it with Rowborough in the parish of Broomfield, connected by beacon on Cotelstone with the earthwork at Norton Fitzwarren commanding the Tone, and so on with the fortress on Castle Neroche. Castle Hill was the most northerly of them

all, and overlooked the Parrett. It was instructive, therefore, to look out for any of the old features of the British earthwork existing there before the mound was occupied by the Norman stronghold. It was not recorded when this stronghold arose. During the reign of Henry VII. there lived at Nether Stowey Sir James Touchet, who led the Cornish insurrection in 1497. Why or when was the castle dismantled? He did not think that it was because of the Cornish insurrection, *i.e.* before 1500 as some would suppose, and it had occurred to him that Lord Audley would hardly have been building a manor or court house below if the castle were standing at the time of the insurrection. Sir A. A. Hood wrote to him (Mr. Greswell) in 1897 as follows:—"Stowey Castle was, I believe, razed to the ground after the execution of Lord Audley. My grandfather (Sir P. P. Acland) had the foundation cleared." He had not yet been able to find any notice of the dismantling, but he thought that Lord Audley himself might have given up his castle and removed his residence from the court house, especially as he was said to have been "a strenuous asserter of the liberty of the subject." Much of the stone of the court appeared to have been brought from the castle hill; some of the stones in the arches seemed too heavy for their object. Mr. Greswell next referred to some interesting local traditions, and mentioned that some old men had told him that they "beat down the castle from Dorsetboro", and then the strong men beat down Stoke Courcy Castle." Stoke Courcy Castle was finally destroyed by Lord Bonville in the reign of Henry VI. for its lawlessness. Could Stowey Castle have suffered the same fate, as local traditions connected the two together? As was usual in connection with ancient encampments and hills, old people had told him that as children they used to be frightened by the giants under castle-hill mound, where there used to be a kind of amphitheatre, and it was stated that bull fights occasionally took place there and local championships at fisticuffs. Mr. Greswell also referred to the proximity of wells which people once resorted to for the cure of bad eyes. The reading of the paper (for which Mr. Greswell was thanked) was followed by applause.

The party was afterwards driven to Quantock Lodge, where they were very hospitably entertained at luncheon by Mr. E. J. Stanley, M.P., this year's president of the Society, who accompanied the members throughout the whole of the day's excursion. The repast, which was partaken of in relays, was of the most *recherché* description, and it need hardly be added that Mr. Stanley and the Hon. Mrs. Stanley did everything they could to promote the comfort of their numerous guests.

Spaxton Church was the next place of resort, and here again Mr. Buckle was invited to give an address. He first pointed out that the east window was a specimen of quite the earliest Geometrical tracery. The only other fragment in the church of an earlier date in the Perpendicular period was a little window which faced the door coming into the porch. They would see that that window was only about half the size of the other two on that side of the wall, and if they went round on the other side they would see that the character of the masonry was entirely changed. At an earlier period of the church the wall was only as high as the little window. At a subsequent period, in the fifteenth century, the walls were raised up to the present height, and the larger windows inserted, and he should imagine that that window was at that time blocked up and opened at a later date. Everything else in the church was of a Perpendicular date, of which the greater part of the Somersetshire churches consisted. In that part of the county they got out of the range of freestone, and they would observe that the arcade was built of the surface stone which came out of the Quantock Hills. The tower was of the rough class he spoke of at Bridgwater, containing no freestone which it was possible to avoid. Referring to the fittings of the church, he pointed out that they consisted of a good deal of oak carving, and that whilst some of the bench end designs were of a distinctly English character, others were distinctly Flemish. In the chancel was a very interesting monument of a knight and his lady, which appeared to belong to the end of the fourteenth century.

The Rev. Mr. Odgers said his friend Mr. Winterbotham had committed to his care a letter which he had received in reply to an inquiry he had addressed to Mr. J. H. Spencer, of Taunton, the architect interested in the restoration of this church, in reference to the beautiful canopied tomb referred to, and Mr. Spencer suggested it belonged either to the Fichtel or Hill family.

Colonel Bramble added that the date of the complete plate armour was about the middle of the fifteenth century.

Blackmoor Manor, adjoining Blackmoor Lane, was the next place visited, and what is known as the old domestic chapel or private place of worship and its surroundings, including some stone carving on the walls and a stone staircase, &c. were viewed with much interest. It was suggested that what is now requisitioned as a bedroom was formerly a pew for the use of the lord and lady of the manor, and was probably provided with a screen front, seating accommodation being provided below

for neighbours during Divine service. Some disappointment was experienced that no description of this was given.

Tea at Brymore was next partaken of at the residence of Mr. Bouverie at that gentleman's invitation, and that and other refreshing beverages, accompanied with an abundant supply of light refreshment, was greatly enjoyed, and even more so a short lounge in the beautifully shaded grounds adjoining the mansion before the party resumed their journey to visit Cannington Church.

Mr. Buckle said those who were present would observe at once on entering it the remarkable character of this building, which was almost unique in this part of the country, its shape being quite different to that generally found in their parish churches. There was only one slate roof which covered the entire building, the nave, aisles and chancel as well, and the result was that the central nave was of tremendous height. They had also a series of extremely lofty arches on both sides of the nave, and beyond that nothing but the bare wall. There were two other churches he knew of in that county which were built in the same form, one (which was the nearest approach to it) being at Norton-sub-Hamdon and the other at Washford, near Exmoor, the latter, however, being on a much humbler scale. Mr. Buckle next alluded to a striking deviation between the direction of the tower and the church, which he remarked was not always like what it was now, and it appeared quite clear that the direction of the Norman-built church was more oblique than at present. The site of the old Cannington nunnery occupied the whole of the adjoining land on the north side. This nunnery of Benedictines was founded in the year 1138 by one of the Courcy family. One suggestion that might be made to account for the obliquity of the present church was that when the nunnery wanted more space for the extension of their building an arrangement was probably made with the authorities at the time of the restoration of the church in consideration of some advantages given to them. In the chapel on the north side was a collection of some very interesting iron railings—a fine specimen of wrought-iron work, of probably 150 years ago or so, which apparently railed in a monument of the Clifford family which previously stood in the chancel. Another thing of great interest consisted in the consecration crosses, twelve of which were to be seen on the south aisle. There were no consecration crosses on the other side, and none on the tower, for the obvious reason that the tower belonged to a later period than the body of the church.

THIRD DAY.

On the third day a large party took part in an excursion to the Sedgmoor district and the country of King Alfred.

Chedzoy.

The church at Chedzoy was described by Mr. Buckle as a very fine example of the Early English style. The two arcades were very interesting and simple examples of that style. The porch, which had been considerably altered, was also Early English, and in the exterior of it were inserted three blocks of stone, one of which bore the initials "R. B.," being those of Richard Bere, the last abbot but one of Glastonbury. His initials would be seen in several places that day. Another stone bore the date 1579. On the south side there had from the first been a very wide aisle, while on the south there was a very narrow aisle. Although it was entirely Perpendicular work, it seemed that the north aisle was never any wider than the present one. At this early period there were transepts, and they had the early pillars remaining. The chancel was also Early English. On the south side there was formerly a chapel, but this had been taken down. The church had always from the thirteenth century been a distinctly important one. In the fifteenth century a clerestory was added to the nave, and there were several minor alterations. The tower at the west end had a remarkably fine arch opening into the nave. The tower, especially in the upper part, was a highly finished one, and here, just two or three miles from Bridgwater, they came to the free-stone towers with their delicate finish. Mr. Buckle pointed out that the buttresses were situated a considerable distance from the tower, and that entire blocks of benches in the nave were in the same position as the original ones. The pulpit had a curious linen-pattern series of panels. There were fragments of old work in the screen and the benches. The most important thing in the church was the embroidery. A magnificent cope was found there some time ago, and it had been converted into three altar frontals. It belonged to a period a little after 1500.

The frontals were shown by the rector, the Rev. Mr. Mullens, and they were of a very beautiful character, representing a series of angels with feathered wings.

Colonel Bramble directed attention to a brass in the north transept. He said it was a nice specimen of a man's armour, and it showed the crest of the De Sydenhams. Its date was probably about 1490.

The visitors also examined the buttresses of the church, on

which tradition says the labourers sharpened their scythes before proceeding to the battle of Sedgmoor.

A drive along the right of the site of the battle of Sedgmoor brought the party to Westonzoyland Church.

Westonzoyland.

Mr. Buckle said the chancel was Early Decorated work. The windows were very elaborate, and some of the tracery was peculiar. Except the chancel the rest of the church was of the Perpendicular period. It was a very fine open and large church, with a magnificent tower at the west end. A prominent feature was the amount of floor space, which gave much dignity to the building. The arcades were elegant, and there was a difference between the two transepts. The initials "R. B." and the Courtenay badge appeared on the outside of the south transept, and it was evident that Glastonbury Abbey had a good deal to do with the erection of the churches of the neighbourhood. The font was a rather remarkable one of the Decorated period, and was a mass of mouldings from the floor to the top. The tower was distinctly the finest they would be visiting this year, and it was enriched from the ground right up to the top. It was built of blue lias stone with Ham Hill dressings. The two stones went together remarkably well, and weathered down to a blue-grey colouring.

Colonel Bramble offered a few remarks on the bells, one of which bears the inscription, "Sancta Anna, ora pro nobis."

Mr. W. George, of Bristol, in speaking of the battle of Sedgmoor, said that after the battle 500 prisoners were crowded into Westonzoyland Church; seventy-five of these were wounded, and five expired within the consecrated walls. Lord Macaulay and other historians did not know that King James II. visited the moor a year after the battle, but such was proved by the parish registers.

Middlezoy.

At Middlezoy Mr. Buckle said the church was remarkable for the geometrical method of the Early English period. In the east window was the most delicate tracery in the world, the mullions of the tracery being only about an inch thick. It was charmingly refined work, and in a good state of preservation. Mr. Buckle pointed out that there was a kind of chancel in the aisle, and there was a low side window.

Colonel Bramble observed that in the East of England such windows were common.

Mr. Buckle said the tower was exceedingly like that of Westonzoyland, only very much smaller. It was remarkably upright, the buttresses being almost perpendicular to the top. There was great delicacy in the work of the chancel, which contained a single miserere.

The visitors inspected the tomb of Louis de Misiers, chevalier, a Frenchman who fell at the battle of Sedgmoor and was buried in the church.

Colonel Bramble showed the communion plate, which includes a particularly handsome silver Elizabethan cup, with the date 1573 upon the cover, and an old pewter flagon.

Othery.

This was the next place visited, and the church was an object of much interest. The interior of the church was in the hands of the whitewashers, who were literally plastering the walls with whitewash and the noble pillars of the church with a yellow composition, causing Colonel Bramble to remark that the order of "pure churchwarden architecture" evidently still prevailed, only in that case there was a little variation provided in the form of yellow.

Mr. Buckle pointed out a curious window in the buttress of the tower, the use of which must have been limited to looking through. It had been suggested that it was to communicate lepers who were not admitted to the church, but he thought this was not so. The tower was entirely different from those they had previously seen, as there was a great slope in the buttresses, causing quite a pyramidal outline. Mr. Buckle pointed out the figures on the tower, which include the Virgin and Child and St. Michael and the Dragon. The date of the tower was about 1500, and the chancel was built early in the thirteenth century. The great feature of the church was that it was a cruciform structure.

Colonel Bramble detailed some of the theories as to low side windows, and said the roof of the church was a fine specimen of the Somerset waggon roof.

The Vicar exhibited a cope, about A.D. 1470, which was found concealed in the pulpit.

Lyng.

After lunch the party proceeded to Lyng.

Mr. Buckle said the church had been unaltered since Mediæval times, except for the fact that necessary repairs had been carried out from time to time, and except a little having been done to the roof, which had been plastered and thus had the oak hidden. Below the plaster the roof was such as they found in many Somerset churches. The edifice, taken gene-

rally, was of a period earlier than the majority of their churches, the main part of it being of a rather transitional character between Decorated and Perpendicular. The tiny side window near the altar was worthy of remark. One of the most interesting features of the church was the very remarkable arrangement which they had for the rood-screen, which formerly filled the whole of the chancel arch. The seats were as they were originally put in. Mr. Buckle also pointed out a curious sedilia in the church.

The Vicar said that church up to 1337 was a chapelry of Athelney Abbey. Whether King Alfred resided at Athelney or not, and whether it was a resting-place for his children, he was intimately connected with Athelney, and they claimed him as the most famous parishioner of Lyng, in which parish Athelney was situated. He was glad they had been able to see the church in an unrestored state. It was his wish to have it restored, and he intended to set about it before long.

North Petherton Church.

This was the last building visited. Mr. Buckle remarked that the great feature of this church was the tower. When he said at Westonzoiland that that was the finest tower he forgot for the moment that they were coming to North Petherton. The Weston tower was an exceedingly fine one, but he thought it must be allowed by everybody that this was a still finer example, for they had there quite one of the most elaborate towers in Somerset. In this case there was no question of taking a slice out of the tower, or taking out a storey and making it higher or lower, for the whole tower from bottom to top was a single conception. The top storey was one mass of ornamentation, and the whole tower was emphatically and distinctly a complete thing and a work of art. Mr. Buckle proceeded to describe somewhat in detail its architectural beauties. With regard to the interior of the church, there was very little of importance to describe, but one of the most interesting features was, perhaps, the fact of the smallness of the piers which carried the chancel arch.

We are indebted to the *Somerset County Gazette* for the report.

THE FURNITURE EXHIBITION, BETHNAL GREEN.

ACCORDING to Mr. T. F. Parkinson, the resident officer in charge of the Bethnal Green Museum, the most important event in this Museum during the year 1896 was the Loan Exhibition of English Furniture and Silks manufactured in the seventeenth and eighteenth centuries. In order to secure the formation of a thoroughly representative collection, a number of gentlemen, well qualified by their knowledge to advise with regard to these branches of industrial art, were invited to act on a committee. This committee met in January 1896, and made several valuable recommendations, which were at once acted upon. Letters inviting loans of furniture and silks were sent, with copies of a memorandum explaining the objects and scope of the exhibition, to the owners of the principal historic houses in England, and to others whose names were suggested by members of the committee, and also to many of the City companies and to the Government departments. To these invitations many favourable replies were received. Mr. J. H. Pollen, M.A., and Mr. C. Purdon Clarke, C.I.E., then visited over seventy different collections in the provinces and in London, and reported upon the various objects offered on loan. Selections were made of the best examples which could be found; these, with the exception of a few objects of large dimensions, were readily lent by the owners. In addition to the letters inviting loans despatched by the Department, a number were addressed personally by H.R.H. the Duchess of Teck, president of the Ladies' Silk Association of Great Britain and Ireland, to her local secretaries, through which means a good collection of eighteenth-century silk dresses was obtained. Altogether 526 pieces of furniture, 95 examples of woven silk fabrics and 250 coloured designs for woven silks from Spitalfields weavers' pattern-books, dated 1727 to 1749, were obtained from 71 owners and exhibited.

The furniture was arranged in chronological order, beginning with the Elizabethan period, in which were many very fine oak chairs, tables, chests, cupboards, &c., at the west end of the north gallery. Jacobean furniture was not differentiated from the Elizabethan in the collection. The Charles I. period was the next group, then Cromwell, Charles II., William and Mary, Queen Anne, Anglo-Dutch and George I. and II.; early, middle, and late George III.; last, furniture made according to the ideas of the Classical Revival, with good examples of the Adam style. A great feature of the collection was the very large number of types of Chippendale chairs, whilst chairs of the Hepplewhite and Sheraton kind were numerous. It was natural as well as suitable to the locality, which is well known as a centre of chairmaking, that chairs should be more numerous than any other description of furniture. There were 280 chairs and settees out of the 526 pieces. The exhibition

was on view to the Press on June 11 and 12. There was a private view on June 13 from 10 A.M. to 6 P.M. At 6 P.M. it was opened to the public.

Throughout the time during which the exhibition was open great interest was taken in it by the local cabinet-makers and even by those in distant parts of England and Scotland; 667 applications were received, chiefly from cabinet-makers, to sketch, to photograph or to make measured drawings of objects in the collection. Many of the visitors expressed the opinion that a better collection of English furniture had never been got together, and some cabinet-makers said it was by far the best they had seen. The number and the variety of types of Chippendale chairs aroused great admiration, and it was a matter of astonishment to many of the local chair-makers that so many types of Chippendale chairs existed. It would seem that such a collection as this would have been even more useful than it was if an illustrated catalogue had been issued at a low price. On several evenings and on some Saturday afternoons and Sundays parties of cabinet-makers and others were taken round the collection by Museum officers, who conducted the parties, giving all information in their power concerning the furniture. These efforts appeared to be appreciated. The number of visitors to the Museum on the 139 days during which the exhibition was open was 157,305, an average of 1,131 on each day. This is only about 50 per diem more than the average for the year, but the number of ordinary regular visitors to the Museum was much diminished during September and October, owing to the wet weather which prevailed at that time. Regret was expressed by many people who came to see the exhibition after it was closed that it had not been more extensively advertised; they had not heard of it until it was closed. It may, however, be stated that bills were posted at the Museum, and were also sent round to be posted at the chief institutions and workshops in the district, and, besides, notices were printed in most of the daily newspapers.

Already the result of the collection is evident in the neighbourhood. Many cabinet-makers work in their own homes and sell their work when it is finished to larger traders. Chairs are seen daily on barrows or handcarts on their way through the streets to be offered for sale; some of these have recently been recognised as very good reproductions of chairs which were in the exhibition. Many more sketches and drawings must have been made than were duly authorised, but in all cases irregular sketching and drawing was stopped when discovered. The Department wrote to all lenders to the collection to ask if they objected to sketches, &c., of their furniture being made, and the very few refusals were respected as far as possible. Messrs. Henry & Co. made reproductions of several pieces for the Vienna Museum of Commerce. Several leading firms of cabinet-makers had men working in the Museum nearly the whole time that the exhibition was open. Each piece of furniture was photographed. A fully descriptive catalogue of the collection, with an introduction by Mr. J. H. Pollen, M.A., has been published.

TESSERÆ.

Masaccio's Financial Condition.

AMONG the acts which had made Giovanni di Bicci de' Medici famous in Florence is one which originated in 1427 and caused much ill blood in the community. He erected the office of the Catasto, invented income-tax schedules, and thus brought together an invaluable store of information as to the lives and property of every individual in the state. Even Masaccio was obliged to make a return of his income and property, and from this document, which shows that he possessed nothing but debts, history has gained not only the date of his birth, but the exact condition in which he lived and the place where he kept his shop. His mother had lost her first husband, and was now the widow of a second called Tedesco di Castel S. Giovanni. Her prospects in life were not brilliant; of her dower 100 florins still remained due. Mona d'Andreuccio di Castel S. Giovanni owed her forty florins, and the executors of her second husband sixty florins, as well as the rent of a vineyard in Castel di S. Giovanni. Beyond these sums in expectancy she possessed not a farthing. On the other hand, Masaccio, who lived with his brother Giovanni, born in 1407, and his mother, born in 1382, though he earned 6 soldi per diem, owed 102 livres 4 soldi to Niccolò di Ser Lapo, a painter, six florins to one Piero Battiloro, and had various articles of property in pledge at the pawn-shops of the "Lion" and the "Cow" (according to other records it appears that poor Masaccio would have to pay interest on these loans at the rate of 50 per cent. per annum). His assistant, Andrea di Giusto, received but irregular pay, and claimed in 1427, for salary in arrears, six florins. The family lived in a house in the quarter S. Croce, for which they paid ten florins a year, and Tommaso kept one of the shops annexed to the old Badia, built, it is said, by Arnolfo near the Palazzo del Podestà, for

which he paid two florins a year. The condition of Masaccio was more favourable, according to his own account, than the reality; Niccolo di Ser Lapo, in his schedule of the year 1427, declares that Tommaso di Ser Giovanni owes him 200 livres, and in a later declaration of 1430, that 68 livres were still due, which he had no hope of ever receiving, as Tommaso had gone to Rome, had died there, and his brother Giovanni pretended that he was not the heir.

Decay of Wood Carvings.

Decay in wood carvings is mainly caused by three species of small beetles of cylindrical form belonging to the family Ptinidæ—*Ptilinus pectinicornis*, *Anobium striatum* and *A. tessellatum*. The ravages of these creatures under favourable circumstances are stated to be such that a new bedstead has been reduced to powder in three years. The complete animal of the genus *Anobium* is known as the "deathwatch," from the noise made by it when at work. Saturation by creosote, when practicable, is effectual to a great extent against these creatures. Fumigation by sulphur, prussic acid, or benzine is believed to be most serviceable, especially if practised when the perfect beetles make their appearance, i.e. the first hot days of summer. Vaporisation by carbolic acid, a pure form of creosote, was tried without entire success; chloroform and benzine were more potent, the fumes of the latter answered, so far as could be ascertained, the purpose in question, and this seems to be the most effectual vaporiser. Saturation with chloride of mercury dissolved in methylated spirits of wine and applied by a brush was next tried, and was found to be undesirable with regard to painted and varnished works on which it may be important to retain the original colour and unpolished surface of the wood; vaporisation by means of benzine rendered saturation unnecessary. The plan of restoring works which had been injured that was adopted by Mr. W. C. Rogers with some carvings by Grinling Gibbons at Belton House, which were seriously attacked, was effectual. This plan consisted of saturating the wood in a strong solution of chloride of mercury; this process injured the colour of the material, and that had to be regained by the use of ammonia and by a slight treatment with muriatic acid. After this, the interior of the wood was injected with vegetable gum and gelatine in order to fill up the worm-holes and strengthen the fabric of the carvings. A varnish of resin, dissolved in spirits of wine, was afterwards spread on the surface.

Thomas Girtin as a Colourist.

Of the subjects which Girtin chose for imitation, his wild mountain scenery and topographical views of old towns were the best adapted for his mode of execution, which was not sufficiently light and elegant for that beautiful style of pastoral and classic landscapes which are so congenial to the feeling and taste of Turner. His masses were bold, broad and abrupt, his touch large and uncontrolled, and not unfrequently too specious to admit of severe criticism. His knowledge of effect, however, was at times exhibited in so captivating a degree that nature, and not art, seemed to prevail throughout the scene which he represented. The variety of light and shadow which he spread over his picturesque buildings, the manner in which he separated the masses, and the brilliancy of certain parts which received a partial burst of sunshine, diffused a splendour of effect to these scenes which no artist before had conceived. His fine taste for colour was most evidently conspicuous in these topographical scenes. Every tint of brick, stone, plaster, timber and tile was combined, both in broad light, medium tint and shadow, with such admirable feeling towards general harmony that no one of the least taste could behold his best productions in this style without admiration and delight. His skies were generally composed either of large masses of clouds, with partial rays of the sun, which gave variety of light and shadow, or else of a serene character, where the whole piece had a general simplicity of effect. His skies were rarely composed of many parts. The azure spaces were washed with a mixture of indigo and lake, and the shadows of the clouds with light red and indigo, Indian red and indigo, and an occasional addition of lake. The warm tone of the cartridge paper frequently served for the lights, without tinting, acquiring additional warmth by being opposed to the cool colour of the azure and shadow of the clouds. His skies in general were extremely luminous. It was a great treat to see this artist at his studies; he was always accessible. When he had accomplished the laying-in of his sky, he would proceed with great facility in the general arrangement of his tints on the buildings, trees, water and other objects. Every colour appeared to be placed with a most judicious perception to effecting a general union or harmony. His light stone tints were put in with thin washes of Roman ochre, the same mixed with light red, and certain spaces free from the warm tints were touched with grey, composed of light red and indigo, or, brighter still, with ultramarine and light red; the brick buildings with Roman ochre, light red and lake, and a mixture of Roman ochre, lake and indigo, or Roman ochre, madder brown and indigo; also with burnt

sienna and Roman ochre, madder brown and Roman ochre, and these colours in all their combinations. For finishing the buildings which came the nearest to the foreground, where the local colour and form were intended to be represented with particular force and effect, Vandyke brown and Cologne-earth were combined with these tints, which gave depth and richness of tones that raised the scale of effect without the least diminution of harmony; on the contrary, the richness of effect was increased from their glowing warmth by neutralising the previous tones, and by throwing them into their respective distances or into proper keeping. The trees which he frequently introduced in his views, exhibiting all the varieties of autumnal hues, he coloured with corresponding harmony to the scale of richness exhibited on his buildings. The greens for these operations were composed of gamboge, indigo and burnt sienna, occasionally heightened with yellow lake, brown pink and gamboge, these mixed too sometimes with Prussian blue; the shadows for the trees with indigo and burnt sienna, and with a most beautiful and harmonious shadow tint composed of grey and madder brown, which perhaps is nearer to the general tone of the shadow of trees than any other combinations that can be formed with water-colours. Girtin made his greys sometimes with Venetian red and indigo, Indian red and indigo, and a useful and most harmonious series of warm and cool greys of Roman ochre, indigo and lake, which, used judiciously, will serve to represent the basis for every species of subject and effect, as viewed in the middle grounds, under the influence of that painter's atmosphere, so prevalent in the autumnal season in our humid climate, which constantly exhibits to the picturesque eye the charms of rich effects in a greater variety than any country in Europe.

Composition in Painting.

In composition four requisites are necessary, that the story be well told, that it possess a good general form, that it be so arranged as to be capable of receiving a proper effect of light and shade, and that it be susceptible of an agreeable disposition of colour. The form of a composition is best suggested by the subject or design, as the fitness of the adaptation ought to appear to emanate from the circumstances themselves; hence the variety of compositions. The point of time being fixed upon, the action, expression and incidental circumstances oblige us often to determine on a particular arrangement, that we may be enabled to place the most interesting objects in the most promising places. Unless our attention be directed to such arrangement in the first instance, we shall often be obliged to put an emphasis on an insignificant object, or throw into repose an interesting point of the action, when we come to consider their relation to a good effect of light and shade. To secure a good general form in composition, it is necessary that it should be as simple as possible. A confused complicated form may hide the art, but can never invite the attention. Horace, in his Art of Poetry, inculcates the same doctrine:—"Denique sit quodvis, simplex duntaxat et unum." Whether this is to be produced by a breadth of light and shade, which is often the case of Rembrandt, even on a most complicated outline, or by the simple arrangement of colour, as we often find in Titian, or by the construction of the group in the first instance, evident in many of Raphael's works, must depend upon the taste of the artist; it is sufficient to direct the younger students to this particular, their minds being generally carried away by notions of variety and contrast.

Dr. Waagen's Opinion of Bath.

Bath is the queen of all the spas in the world, for there are certainly very few which can compare with it for beauty of situation, and none for magnificence of buildings. The city arises in terraces from the banks of the Avon, which winds through the valley, to the top of the Lansdown, a pretty steep eminence, about 800 feet high. The vast masses of architecture rising one above the other have a highly picturesque and striking effect when seen from the valley. The eye is chiefly attracted by the Royal Crescent, situated about half-way up the hill, and Lansdown Crescent, which towers above all. This is the name given in England to large masses of building, the façades of which gradually recede from the ends to the centre, so as to form a curve more or less near to a semicircle, a mode of building which is certainly very objectionable in its principle; they contain a larger or smaller number of dwellings for single families. The impression of grandeur and solidity is enhanced by the material, which is a stone found in the neighbourhood. Yet the various views from the several points of elevation, particularly Lansdown Terrace and King's Terrace, are almost more beautiful and worth seeing. From the first you have a view over the whole rich valley, with the finely wooded eminences that rise on the other bank of the Avon, and the whole world of buildings more or less elevated above the plain. The Gothic abbey which, with its tower, rises peacefully quite down in the valley, near the banks of the Avon, has in point of view a most picturesque effect. The whole, too, has such a southern character, the air is so deliciously mild, that

one fancies oneself in Italy, and cannot wonder that even the piratical Romans appreciated the advantages of this situation with the warm baths.

Water-Colour Landscapes.

In morning and evening effects we naturally look towards the light, which at those periods of the day is marked by a mild beauty which gratifies and attracts, yet divested of that dazzling noontide effulgence which weakens and repulses the eye. Those objects which are seen against the strongest light must wear a neutral tint, which may be termed negative harmony; for were they to be garbed in the rich and full dress liveries of nature, the influence of the lustres behind them would in a great measure be rendered nugatory and the effect weak and full of error. On the contrary, in the representation of broad sunshine or mid-day, those parts of the piece which are visited by, but not seen against, strong lights, will admit of a rich and beautiful harmony of colour without doing violence to truth or infringing on the economy of nature, and this may be called positive harmony, or a picture of colour. Every tint should be laid on with clearness and decision, so that the object may receive its proper tone at the first touch of the hair pencil; nor is less skill required in the choice and appropriation of the colours, which should be diversified as much as is consistent with the unison necessary to the 'production' of harmony. Objects which are exposed to the light require a higher finish and more flowing warmth of colour than those which are shrouded in shade; while the minutest parts of the former ought to be touched with the utmost care, so as to render visible and striking all that the broad and bright radiance of the sun might be supposed to develop. The latter will admit of a less laboured and less perfect delineation. In the lights of a picture attention to this rule is indispensable where it is necessary to distinguish, with so much correctness of detail, those very objects which in shadow would permit that intimacy of union which would almost make them appear as one. The light aerial tints should be laid on the remotest parts of a picture, gradually brightening into more rich and decided tones as they approach the nearer and more prominent objects, taking care to preserve the same atmosphere throughout the picture.

Curved and Straight Lines.

The great horizontal lines formed by regular layers of worked stone, as in the huge temples of Egypt, give an impression of solidity, of duration to eternity. Nothing, on the other hand, can be gayer than the pagodas of the Chinese, with their roofs curled upwards at the extremities—a graceful combination of the curve and the oblique. This form is to be found also in the shape of their shoes and of their head-dresses, and, stranger still, in the features of their faces. Again, nothing can be more doleful than the immense roofs of the countries of snow and ice, whose sides descend nearly to the ground by two dull and rigid lines, forming an acute angle, and stretching out from the side walls as if to enclose and smother the houses which they protect. This mode of construction still prevails in northern climes. A century ago no other was employed in the villages. The houses, which were nothing but a ground floor, disappeared beneath the thick and heavy thatched roofs, the projection of which kept out the day and gave them the appearance of being covered by an extinguisher. It is easily understood how the deliberate and clearly meant predominance of one or the other of these lines can determine, with great precision, what impression a work of art shall produce, while their skilful combination can soften or modify it to the taste of the artist. But there is as much danger in exaggeration in the one direction as in the other. If the too frequent repetition of similar lines repels by its monotony, the abuse of contrasting lines ends in a neutralisation of one impression by another, that is to say, in a total want of meaning.

Pointed and Semicircular Arches.

According to the "Théorie des Constructions," by Rondelet, the thrust of a pointed arch, compared to that of a semicircular one, is *ceteris paribus* as three to seven; and again, the weight of a pointed arch upon its supports, as compared with that of a semicircular arch, is as three to four—a result due to the sharp form of its summit and its tapering sides. From these facts it follows that the substitution of the pointed for the semicircular form rendered it possible to construct churches both lighter and higher than before, without any increase either of expense or of labour; and increased height was the great object of desire. The Orientals, with the exception of the Babylonians, sought to obtain effect by greatness of detail and immense horizontal dimensions; the nations of the west, on the other hand, pinned their faith to grandeur of vertical lines and proportions. Another improvement, not perhaps so striking at first sight, but nevertheless very considerable, contributed to increase the advantage offered by the pointed form of construction. The Romans very frequently employed ribbed vaults; but they did not place the ribs where they were most wanted—along the

angles of the diagonal groins—so they were compelled to build all their vaults, even minor ones, with heavy materials, the formidable thrust of which demanded walls and piers of great thickness. The introduction of the diagonal ribs gave a double advantage—first, it permitted the employment of very light materials, and secondly, it enabled all the weight to be so arranged as to fall upon four predetermined points.

The Nude in Greek Art.

SIR,—It is not my desire to unnecessarily prolong the discussion of this subject, but I would again ask for your indulgence in allowing me to have an opportunity of answering the "charges" brought against me in the diatribe which appears in your issue of the 13th inst. signed "A Lady Artist" with reference to my previous letter, and to, if possible, more clearly express my meaning, which, apparently, your correspondent quite fails to grasp.

I, to a certain extent, admire "A Lady Artist" for the spirited manner in which she takes up the cudgels in defence of her sisters in art, though whatever may be the merits or demerits of my opinions from her point of view, as regards the quality of her reply, I will refrain from comment.

"He seems anxious to have all figures draped. Imagine Apollo with a tall hat," &c. This one expression is sufficient to show that I have not been clearly understood; such ideas have never entered my mind. "Of course a sculptor does not look at a figure from a medical point of view." I never dreamt that he did. "He displays such a lamentable amount of ignorance of art."

I have written, believe me, conscientiously, and not without observation or experience of the matter.

What I submit is this. Though the study of the nude is a necessity, perhaps, for the production of even draped figures, the study from the *absolute* nude, which amounts to gross vulgarity, is *not* a necessity.

The countenancing of the study from statues with no attempt at covering, however slight, upon them, in public buildings where children, and young girls especially, are freely admitted, conduces to the lowering of the moral status. The publication of drawings, &c., of entirely nude (especially female) figures conduces to the same end.

I submit the foregoing to thinking men, and must emphatically reiterate the contents of my former letter, at the risk of calling down upon me the wrath of the anomalous "new woman," and even under the shadow of the dreadful mahlstick with which my fair opponent threatens me. With apologies for once more encroaching upon your space, I remain, Sir, your very obedient servant,

RONALD KELLY.

16 Southampton Street, Fitzroy Square, W.:

August 16, 1897.

GENERAL.

Mr. E. Moir, the agent of Messrs. S. Pearson & Son, the contractors, during the construction of the Blackwall Tunnel, has been presented by the staff engaged on the tunnel with a pair of handsome silver candelabra as a mark of esteem and a souvenir of his association with this great engineering triumph.

The Gloucester Union Board of Guardians have appointed Mr. Alfred Saxon Snell, of London, and Mr. Walter B. Wood, of Gloucester, as joint-architects to their proposed new workhouse, infirmary and cottage homes.

The Playing-Card Makers' Company offer the "H. D. Philips prize", of 5*l.* 5*s.* for the best special design for the backs of playing-cards, intended for presentation by the Company to its guests at the banquet of the masters and wardens in November next. Two other prizes of 3*l.* 3*s.* and 2*l.* 2*s.* respectively are offered by the company for the two next best of such designs. The designs must be in colour and be such as can be reproduced effectively in not more than six printings. The arms of the Company and the City of London are to form a portion of the design. Designs must be sent not later than September 27 next to the clerk of the Company.

A Process invented by Colonel Duilier is being tried at the South Kensington Museum in order to get rid of the smoke produced by the boilers of the electric-lighting installation. It consists in introducing jets of water into the flue. The quantity of smoke has been lessened, and by a further modification of the apparatus, which is now being made by the inventor, it is hoped that it may be almost if not entirely removed.

The Architect.

THE WEEK.

THE terms of the settlement of the Penrhyn Quarry dispute are considered to be most satisfactory by the men. But to those who judge the contest from a distance the victory does not appear to be worth the sacrifice of a year's labour. Similar conditions could have been obtained by the men many months ago. The standard wage continues to be 5s. 6d. a day. The men can make their grievances known direct to the chief manager, and can even appeal to Lord PENRHYN himself. Contracts are not abolished, but the management undertake that each employé under one shall receive his just ratio of wages. The workmen can be readmitted in a body, or as soon as work can be arranged for them. This last point is considered of much importance, for it was expected that individual supplications for employment would be necessary. If both parties are satisfied and treat their losses as trifles there is hope for the future. But architects and builders cannot have the old confidence in quarries which can cease to be productive through insignificant causes. The strike has brought rivals to the fore, and the trade will therefore be carried on henceforth with unaccustomed competition.

IT is a remarkable fact that the ten selected contractors who were invited by the Municipality of Paris to tender for the metalwork of the Pont Alexandre III. over the Seine have declined. The conditions were supposed to be too exacting. In a work of the kind the French character would be at stake, and remembering the collapse of the new bridge at Tarbes while it was being tested, the Municipality were right to insist on the best work in steel that is obtainable. The hesitation of the contractors to accept the specification in its entirety suggests a decline in morals. If the Paris Municipal Council were wise they would risk the consequences, and invite half a dozen or ten English contractors to send in tenders; in that way an object-lesson would be afforded to French constructors, and one of which they stand in need.

IT may not be known to all our readers that a committee of the British Association are co-operating with the Silchester Excavation Fund committee in their explorations. According to the report, the area selected for excavation in 1896 included two insulæ (XV. and XVI.), immediately south of insulæ XIII. and XIV., which were excavated in 1895. The result was, on the whole, satisfactory, and as usual ended in some curious and totally unexpected discoveries. Insula XV. appears, like insulæ IX., X., XI., XII. and XIII., to have been given up to the dyeing industry, of which traces were found in 1894 and 1895, and a large area in the northern part of the insula was perhaps used as a bleaching-ground. Two wells were discovered, one with a wooden framing at the bottom, the other with a large wooden tub, which will be added with other antiquities to the Silchester Loan Collection in the Reading Museum. Insula XVI. contained a large and important house of the courtyard type in the north-west angle, and two other houses of the corridor type, as well as an isolated square building. Traces were also found of other structures, which were probably of wood. A large number of pits were met with in the trenches, and from these some good vessels of pottery and other antiquities were recovered. A pit of unusual size near the south-east angle yielded a large quantity of bladebones of sheep; the numerous perforations in these showed that they had been used in the manufacture of counters. Besides the operations in insulæ XV. and XVI., a small area was trenched to the south of the parish graveyard, which is within the walls, in view of its immediate inclosure as an additional burying ground. The area is close to the two square temples uncovered in 1890. The foundations of a small house of the corridor type were disclosed, near which was found a lump of worked porphyry. It is proposed during the current year to excavate the two insulæ (XVI. and XVII.) extending from insula III. as far as the south wall.

Although more than half of the area (100 acres) within the walls has now been systematically excavated, and with most important results, the committee desire to point out that there is still several more years' work to be done before the Romano-British city can be regarded as completely disclosed.

THERE is a complaint that the ancient oak roof of Bebington Church, near Liverpool, has been removed in the course of the restoration. It is true there is decay apparent in many of the timbers, but the conclusion of more than one who surveyed it is that it was quite capable of repair, and need not have been demolished. Decay in English oak timber, says Mr. E. W. Cox in referring to the roof, has some peculiarities; while the inner heart of the well-matured wood will remain sound for many centuries, the external rings of growth on the tree, technically called the sap wood, for an inch or two are less enduring and liable to decay and attacks of the worms. The cutting out of such wood should be done at first, but should any be left in and decay it is quite easy to cut it out and repair it without in any way affecting the heart of the wood. The sawing of the apparently rotten timbers, which are exhibited as a justification for this destruction, has disclosed that the decay in this roof is to a great degree superficial, and therefore capable of repair. Most of the joints are as sound as the day they were made, and both the material and construction of the framing of the timbers are superior to what is being substituted.

ON May 31, 1895, the following ordinance relating to windows projecting beyond the building line was adopted by the mayor, aldermen and commonalty of the city of New York:—"Bay windows, oriel windows, or other windows of any dwelling heretofore or hereafter constructed may extend not more than 1 foot beyond the street or building line. Show or bow windows may be placed in front of any store window opening, provided, however, that any such window shall not start from the ground or level of the platform and is at least 18 inches above the same to the sill, and is supported on suitable brackets, and shall not extend above the first storey, nor more than 12 inches from the front wall of the building to which it is attached, nor more than 12 inches beyond the jambs or posts at the sides of the openings. Every window in this section mentioned shall in all respects conform to the laws regulating the erection of buildings in the city of New York. The penalty for violation of this ordinance shall be 100 dollars." The value of the ordinance has since been tested, and apparently it is of little avail. In February of the present year an action was brought by the Department of Buildings against a person named Dick, and the judge decided against him. He appealed, but before the case was again tried the Appellate Division gave a decision in another case (BROADBELT v. LOEW) relating to frontages, but whether it was declared that the ordinance was valid or not lawyers are unable to determine. The appeal in the Dick case was afterwards heard and the judgment of the lower court affirmed. In this state of uncertainty and confusion the acting counsel to the Corporation maintains that the Dick case does not affect the ruling in the Broadbelt case, for the reason that there were two points in the Dick case, one being the same as that involved in the Broadbelt case and another entirely different, upon either one of which the court could act in rendering a decision. From unofficial sources he believes that the court did not intend to overrule or question the decision in the case of BROADBELT v. LOEW. The officials therefore conclude that the effect of the decision in BROADBELT v. LOEW is that the ordinance in question is valid, and the effect of the case of the Department of Buildings v. DICK is that where a person fails to show the proposed window upon his plans and in his specifications, and thereafter erects the window, such person is liable as for a penalty for a violation of the building law. These two decisions, thus taken together, make it imperative that in the present state of the law the proposed window should be shown. Unofficial lawyers, no doubt, take another view of the situation, and it is evident the building regulations of New York are more dubious than those of London.

ARCHÆOLOGY AND ANTIQUARIANISM.

THESE is one passage in the address of the President of the British Association which does not appear to have received any attention from the critics, although it may have more interest for architects and lovers of what is commonly known as antiquity than those parts which appealed to students of physical science. It is one where Sir JOHN EVANS endeavoured to suggest that prehistoric archaeology, of which he is a distinguished representative, is worthy of the notice of such an assembly as met in Toronto, whilst the study of the archaeology of a later period was only a sort of *dilettante* pastime which was adapted to the weaklings who follow belles-lettres. His words were:—"A distinction does exist between archaeology proper and what, for want of a better word, may be termed antiquarianism. It may be interesting to know the internal arrangements of a Dominican convent in the Middle Ages; to distinguish between the different mouldings characteristic of the principal styles of Gothic architecture; to determine whether an English coin bearing the name of Henry was struck under HENRY II., RICHARD, JOHN, or HENRY III.; or to decide whether some given edifice was erected in Roman, Saxon, or Norman times. But the power to do this, though involving no small degree of detailed knowledge and some acquaintance with scientific methods, can hardly entitle its possessors to be enrolled among the votaries of science." The spirit which animates the words is manifest. Evidently Sir JOHN EVANS is eager to see his own favourite study placed on the same level with chemistry, electricity, mathematics and other sciences, for although in the British Association there is a section of anthropology, it is a late creation which BREWSTER and the founders of the Association did not foresee, or they would have taken measures to secure its exclusion. There are a great many members who tolerate anthropology because it is believed to appeal to untrained minds, and helps to attract subscribing associates who would be scared by discoveries in pure mathematics or speculations about atoms. It is also so comprehensive that, by the exercise of diplomacy, a paper on a Greek temple could be read in the section. For our part, we do not intend to say one word against the section or against prehistoric archaeology, but we maintain that archaeology relating to a later period likewise offers opportunities for the co-operation of the sciences, and there was no need for the President to sacrifice architecture or numismatics for the sake of a hobby. This will be more evident by a short consideration of what science and archaeology signify.

A definition of science which will be universally acceptable remains to be formed. When BACON translated "Advancement of Learning" by "De Augmentis Scientiarum," he was only employing a phrase that was familiar in his time. Science was then an equivalent for knowledge or learning, and it was accepted in the same sense long afterwards. Sir JOHN HERSCHEL, for instance, defines science as the knowledge of many scholars presented in such a form as to be accessible for all. But so much passes for knowledge which can hardly be considered as scientific, there is a desire for a more explicit connoting definition. In the same way it is no less difficult to distinguish between ancient and modern times, or to put limits to archaeology. There is much which belongs to the present century which, if brought under the notice of people now living, would seem to be as ancient as anything belonging to the times of the PHARAOHS. We may, however, assume that works of the nineteenth century do not come within the purview of the archaeologist.

Without attempting a new definition of science, we can say that the word is now assumed to signify that kind of knowledge which is certain, that is determined by as rigorous logic as can be employed, and assuming that all the tests which the phenomena of the subject will allow have been applied. In course of time more exact tests will be used, and therefore certainty is only comparative unless in a few cases. COMTE was wise when in dealing with concrete sciences, such as mineralogy, botany and zoology, he considered them as not yet formed, but he would not deny that our knowledge of them exemplified the Positive method as far as it was understood by the uninitiated. It is the hope of establishing that certainty which compels so many theorists to endeavour to seek a

scientific basis for subjects which at first view would be considered as opposed to science. The laws of thought have been declared to be as inflexible as gravitation, and books on logic have appeared which consist solely of algebraic formulæ. Political economy, although apparently always changing, is considered by its votaries to be a very exact science. Poetry also is not excluded from the influence of science, and those who insist on a rigid system of proportions and the observance of stereotyped academic laws in the arts, are they not aping the conditions of science?

The students of prehistoric archaeology are accordingly not to be censured if they insist that they are students of science. It must be allowed that it is very hard to draw a line between them and geologists and palæontologists. Experts cannot always say whether a fragment of flint is an ancient weapon, or what is left of a nodule after it has been subjected to the wear and tear of time, water and the atmosphere. Sir JOHN EVANS, in the address he delivered last week, informed the Canadians that "within the last few months we have had the report of worked flints having been discovered in the late Pliocene forest bed of Norfolk, but in that instance the signs of human workmanship upon the flints are by no means apparent to all observers." The bed in question is almost modern, if compared with some in which flints have been found; but while the archaeologists maintain they were tools or weapons, the geologists are no less convinced they were never used to kill bipeds or quadrupeds. It can hardly be upheld that the man who seeks for flints in the hope of discovering evidence of the antiquity of man is not a votary of science, but a mere antiquarian, like those who hunt curiosity shops for treasures; while he who looks for flints as evidence of the order of the succession of strata can claim to be inspired by BACON's or NEWTON's spirit. The geological and archaeological problems correspond. It is puzzling to find beds of rock far apart which are identical in construction and characterised by similar fossils. But a still greater puzzle is presented for solution when we discover "that man at two such remote epochs as the pre-glacial and the post-glacial should have manufactured implements so identical in character that they cannot be distinguished apart," although an interval which is not to be measured by years separates the epochs. There is also a wonderful analogy between nature's direct operations as seen in strata and her operations through the agency of man when we perceive no difference between the implements unearthed in Britain and those met with in France, Italy, Spain, Portugal, Egypt, &c., nay in Somaliland, for "in an ancient river valley, at a great elevation above the sea, Mr. SETON-KARR has collected a large number of implements formed of flint and quartzite which, judging from their form and character, might have been dug out of the drift deposits of the Somme or the Seine, the Thames or the ancient Solent." In all such cases, flint-hunting corresponds with fossil-hunting, and if the palæontologist can claim to be of a scientific stock, the prehistoric archaeologist is either representative of the same family or of one that is near akin to it.

If uniformity is a characteristic of the flint weapons, the same quality is to be found in many of the early forms which are sought after by the antiquary. After all, man is not a remarkably inventive animal, and when analysed the arts and manufactures of our own time are found to be made up of operations which little by little were derived from earlier efforts. A few forms of weapons and utensils have been faithfully followed for ages, and what is more extraordinary, primitive ornamentation was as restricted as primitive construction. A great step was supposed to be made by those who attempted to trace the history of art, when Celtic interlacings were traced to Norway and Iceland. But before reaching those countries the patterns had travelled over Europe, parts of Asia and Africa, and nobody can say where they originated. As long as the fret was accepted as Greek it was a hallowed form, and inspired a great deal of acute speculation; since it was found to have served many a meaner race it has lost all interest. Other patterns are doomed to a like fate.

At the present time it is not apparent how any of the sections of the British Association could help in elucidating the origin of the earliest forms of ornament. When a bone is found in a cave on the borders of Derbyshire and Nottinghamshire with the figure of a horse scratched on it,

there is no difficulty in concluding that as it resembles similar figures found in French caves there was some affinity between the artists. But ornament which is seen in lands far apart presents more difficulties, and caution is needed before any inferences are arrived at. It cannot be said that prehistoric archaeology can reckon on more aid from science. No doubt the question of time is one which is beyond our arithmetic, and the transformations of the earth's surface were of a kind which sometimes make geological periods appear to be intermingled, whatever the cause. Sir JOHN EVANS is compelled after years of toil to draw on his imagination when he wishes to attempt a sort of outline of the history of the human race. "Is it not a case," he asks, "in which imagination may be fairly invoked in aid of science? May we not picture to ourselves our earliest ancestors gradually developing from a lowly origin acquiring a taste for hunting? May we not imagine the game for the hunter becoming scarcer, and that his life in consequence assumed a more nomadic character"—and so on? But how can he attain certainty by imagining and picture-making? Science has not supplied the information which is necessary for trustworthy answers to the questions, and similar speculations were indulged in before the British Association was established. From this it will be seen that prehistoric archaeology is not much indebted to the older sections of the Association, nor is there a prospect of any change which will impart additional value to flint instruments.

Let us now consider the inferior archaeology or antiquarianism, which Sir JOHN EVANS will not designate as "archæology proper." We shall take his own cases. "The internal arrangements of a Dominican convent in the Middle Ages" would, of course, comprise the subject of building construction. The section of mechanics or engineering could co-operate in treating it according to modern principles. Professor WILLIS was the highest authority on mechanics in his time. He was Jacksonian Professor in the University of Cambridge, and whenever the Government were in a difficulty his aid was invoked. WILLIS was not afraid that any imputation of antiquarianism would injure his reputation as a specialist or as a professor, or, we might add, diminish his influence on members of the British Association. His treatise "On the Construction of the Vaults of the Middle Ages" would have been well received if read at one of the meetings of the Association, for it would have interest for students of science who were never likely to have designed an arch. To him we are indebted for the revelation of the internal arrangements of a Benedictine convent at Canterbury, and he would enter with zest into an investigation of a Dominican convent, for that order endeavoured to satisfy the desire of modern as well as Mediæval congregations by building churches without piers or columns to obstruct the view. Mediæval masonry need not be without interest to the geologist and chemist, the ornament is worth the attention of the botanist, and it cannot be said there is no more to be discovered by chemistry about stained glass than is already furnished by artists and amateurs. The American professor who has revealed so much relating to the substitution of curved for straight lines suggests there are problems in building which await the solution of physiologists. Nor are mouldings so insignificant as Sir JOHN EVANS would suppose. As clues towards identification they are comparable for certainty with those utilised by geologists.

What Sir JOHN EVANS says about coins reveals the strength of prejudice and its weakness also. To determine the age of a coin which is dateless does not entitle an investigator to be enrolled as a votary of science, although he may employ chemistry in order to discover the proportions of the materials used. But when the same chemical process is employed on a relic of the Iron or Bronze Age, or when coins are treated as fossils, and their morphology studied, then the investigator can plume himself as a fellow-labourer with CHARLES DARWIN. From the President's conclusions it would seem as if a study of prehistoric archaeology may excite the imagination, but it does not always improve the reasoning machinery in man.

If we find that, as occurred in Toronto, archaeology and architecture, for the two are closely related, are treated by the British Association as coming nearer to literature than to science, the cause is to be traced to the indifference of architects. They avoided the meetings, while the civil

engineers were allowed to appear as the only representatives of construction. It will hardly be credited that, during a period of about half a century, the late CUTHBERT BRODRICK, of Leeds, was the only architect who possessed sufficient courage to read a paper, his subject being the dome of his town hall. When the representatives of architecture have kept aloof, are men of science to be blamed if they are oblivious of any connection between their own subjects and buildings, whether ancient or modern, monastic or pagan?

ELECTRICITY METERS.

TWO papers on this subject were recently read at a meeting of the Municipal Electrical Association, one dealing more with prepayment meters.

In one paper a list of "essentials" for a really good meter was given. They are:—Accuracy, durability, low starting current, noiselessness, impossibility of being tampered with by consumers, unaffected by stray magnetic fields, reduction of moving parts to a minimum, small loss of power, absence of clockwork, liquids likely to freeze, mercury, contacts or commutators. If energy meters they must measure true watts. They must be unaffected by vibration, alteration of temperature, frequency (if alternating), or barometric pressure.

"In addition, the following may be classed as 'desiderata':—Equally correct for direct or alternating currents, capable of being checked by a short time test, low cost."

We have no hesitation in saying that the really good meter has yet to arrive if the above list of essentials is to be taken as correct. At the present time one might be satisfied with a rather less difficult standard, as the above may frighten inventors.

Some interesting figures were given with reference to the accuracy of gas and water meters. The former are said to have an error "of not more than 2 per cent. in favour of the seller and 3 per cent. in favour of the consumer" when new. Water meters are said to be correct within $2\frac{1}{2}$ per cent. of the mean. It was also stated that most modern electricity meters are correct to the same extent.

The limits allowed by the author are:—

At full or half load	2 per cent. from the normal.
At quarter load	3 " " " "
At one-tenth load	4 " " " "

The author rightly insists that the law which governs a meter should be a correct one, not an incorrect one "cooked" by numerous compensating devices to approximately correct readings.

With regard to reliability of meters, several points were mentioned as defects of many meters, and one is the use of a tinned iron case. It was pointed out that these cases cannot be made dust-tight, while a substantial cast-iron one can. Another point is the use of iron or steel in the recording train of wheels. This should be avoided, as slight rusting may stop the meter.

The really great defect of motor meters is the high current required to start them, and this defect is one which it is difficult to overcome satisfactorily. The limit of current above which the meter must (in the author's opinion) start is one-fiftieth of the maximum load.

Several devices for assisting meters to start were described, but they are nearly all rather liable to cause the meter to run when there is no load. This latter defect is one which, in the interests of the public, should be entirely obliterated and made impossible. It is distinctly annoying to find that the meter registers a hundred units or so when the house has been shut up since the meter was last read.

The author does not quite make out his case when he says that "It is hardly necessary to observe that any form of meter that requires periodical winding up should be avoided." Meters are now regularly inspected monthly, or at most three-monthly, and there is no difficulty in winding up the clock. It is well known that, as far as measuring quantities goes, the clock is of all instruments the most accurate. Mr. WILMSHURST (the author) would debar the use of this instrument simply because of the trouble of winding, thus throwing out of court the meter which is probably the most accurate of all. The Aron clock-meter starts with the smallest load, and is very accurate through the entire range.

The effect of vibration in assisting motor meters to start

was discussed briefly. The really greater error in meters, the temperature error, is scarcely mentioned, and we think this a very grave omission in a paper of this class. The temperature error in motor meters is far more serious than usually imagined, and is seldom tested. In the particulars of tests there was no temperature test, although other experimenters were referred to. Temperature has a great effect on most meters.

The next point of interest mentioned was in connection with the alternating current meter, whether it should be a quantity or an energy meter. The author very rightly comes to the conclusion that it should be an energy meter, as the error in favour of the suppliers is very great if apparatus with self-induction is used.

There are supposed to be about 100,000 meters at present in use in this country, 70 per cent. being of the quantity type.

The author has made a number of experiments with energy and quantity meters, as to the revenue they bring in.

In one case where the voltage was 2 per cent. high, and where some lamps were burning all day, the energy meter registered 1,445 units, and the quantity meter 1,375 units; and in another where one or two lights were in use eight hours, and eight lights in use two hours, the energy meter registered 23 and the quantity meter 18 units.

In every case where there were a few lamps on for many hours the energy meter was much more accurate than the quantity meter. This is because the former meters read more accurately at low loads.

A good technical description was given of the new Westinghouse energy meter, but it is not of general interest.

The works tests should, in the author's opinion, include the following:—Accuracy at one-tenth, half, and full load, starting current, running on shunt with and without vibration and slightly increased pressure, energy lost in shunt (if any), volts lost in meter at full load, insulation of meter, and, we would add, temperature error.

The other paper, dealing more with prepayment meters, was not so accurate as the one on meters in general, but still there were many good points mentioned. The author (Mr. COUZENS) very rightly points out that the poorer thickly-populated districts offer a far better field for extension of mains if the consumers can be charged for their supply in a proper manner, and the author thinks that the proper method of charging is by prepayment meters, in connection with free wiring. The reasons and economy of these systems were gone into fully in our columns a few weeks ago, and there is therefore no need to enlarge upon them here.

The author, after going into the advantages of prepayment meters, pointed to the great success attained by their use in London and elsewhere, especially by the Gas Light and Coke Company, who had on their books a short time ago 150,000 prepayment customers, and from 16,000 to 17,000 waiting to be connected up. When the author goes into the technical points of prepayment meters we think he is not very accurate. He gives the essential features of a prepayment meter as being:—Cheap (not more than 50s. each), reliable, solid, and strong, capable of storing up several pennyworths, and should be fairly accurate, though an error of up to 5 per cent. is allowable; and also "that it should be a watt meter rather than an ampère hour meter, as any deviation of the voltage from the normal will have an appreciable effect on the duration of the pennyworth. It must also be proof against being tampered with, and there must be no practicable means by which ingenious contrivances can be made to extract an unlimited supply with a single coin, as is the case with the automatic sweetmeat machines at present. The prepayment meter will not have the advantage of the public gaze to defend it from these frauds." The author also thinks that a purely prepayment meter is wanted, not a mere attachment to an ordinary meter. This is where we think the author is wrong. A penny-in-the-slot meter must essentially be a meter with a slot and switch, and a cheap meter must first be made, fairly accurate, and until this is done a cheap penny-in-the-slot meter is out of the question. Also given an ordinary meter with dials and a slot attachment, there is no fear of fraud. If the amount of money in the box does

not correspond to the quantity consumed there will be an obvious way of enforcing payment. By this arrangement any vagaries of the attachment or of the consumer can be checked.

The author then described the BASTIAN and HODGES prepayment device attached to an ordinary meter, and he said: "This constitutes a kind of half-way house between the ordinary meter and the prepayment meter pure and simple." And, "Regarding solely prepayment meters, though at present there are none actually on the market, almost everyone has some type or other just emerging from the chrysalis stage."

The ELLIS and ATHERTON prepayment meter was then described. This will shortly be on the market and is to be very cheap. We anxiously await tests, as we should think from the description that it would not be very accurate, but we hope we may be disappointed.

These two pioneer arrangements have not been described here, as it is difficult to clearly explain their working without sketches.

It is fairly certain that there will be many inventors who will take up this matter, and we may expect more types of prepayment meters very soon, but we think it will be some time before a really good cheap meter, whether with or without a prepayment device, is on the market. When it does come, however, it will have a great future.

MEGALITHIC BUILDERS.

IN the last number of the *Evergreen* Professor Patrick Geddes, of Edinburgh, had an interesting and suggestive article entitled "The Megalithic Builders." The Professor gives a rapid review of the present-day architecture in Scotland. He sets out in Glenmoriston, and describes the following scene there:—

We crossed the loch, left our boat and went up the glen. Passing the castle with its medley of new and old we stopped at the little cemetery. A pair of tall standing stones, a linden avenue, then another pair of monoliths gave worthy entrance to the grove of rest, with its grassy mounds, its massive tombstones of a long dynasty of chiefs and the many-stoned, almost cairn-built, tomb of their hereditary pipers. Castle and glen are empty now and the pipes are silent; but here at least, after love and life, after labour and war, and the music of all these the silence is of unsaddening peace.

We chose the right bank of the river (the road is on the left) and trudged on through pretty scenery of the familiar sort—hill in cloud and sunshine, river in ripple and race, birch and bracken, heather and pine, with every here and there a granite boulder among a group of stunted junipers. But a couple of hours up the stream a scene opened out, of which neither my painter friend nor myself had seen the like before. The trees grew less thickly, the heathery hillside receded, and there lay before us broad park-like grassy levels with vast masses of evergreen, here in rounded masses, there rising into graceful spires. The first impression was almost that of park and shrubbery laid out by a skilful landscape gardener of old for some unbuilt mansion, but as we came nearer it was clearly a natural glade of gigantic junipers. Tall and massive, ancient and rugged, gnarled and broken, their green spirelets rose over deep caverns of shadow, filled with writhing arms breaking through vast lichenous growths, some of hoary dishevelled age, others in broad wrinkled overlappings of strange greens and lurid blues, a gorgeous ragged foulness like a witch's draperies. Outside these shadowed hollows the scene had the melancholy beauty of a cypress cemetery in the East. And who might not one of those boulders cover? As we went on the sky was grey, and a sobbing linn settled into black pools of sorrow: we had passed the place of sighing, but here seemed the wells of the river of tears.

Soon we came to a rotting bridge, and crossed to a ruined mill, with tumbled stone heaps that not so long ago were cottages and byres; for though dramatic evictions are out of fashion, it remains more than ever the interest of any practical-minded laird (chief no longer) quietly to depopulate his glen, and as the old folks die out, throw their crofts into the forest; for the fewer the people the more winged and four-footed people, and the more rent his shooting lodger will be willing to pay.

Yet in this desolation we found a single child, a quiet wee lassie, I suppose the gamekeeper's, playing alone. It was useless speaking to her, for the education code practically works so that the children nowadays lose their Gaelic without really learning English. She did not even lift her head to look at us, but went steadily on with her playthings—a gathering of rough stones. We stepped nearer to see what she was doing with them. A shudder of astonishment ran through us—the child

had traced out a ruined sheepfold, and was building beside it a funeral cairn.

We could scarcely believe our eyes or our interpretation, but the thing was unmistakable, indisputable; and so leaving hamlet and its monument builder, we went on to the narrowing of the glen. There the explanation broke upon us; at the opening of a new labyrinth of junipers was standing; or rather slipping down, a moss-grown cairn—another and another, a group, a score, a hundred, each a recorded sorrow of the glen. The bairn with her stones was not inventing her ghastly game, but only reproducing her near and familiar impressions; yet, child historian, child artist, she had combined for us the story of a passing race, a megalithic people, the utter winter of their disappearance seemingly nigh at hand.

The Professor then passes to Inverness. He writes:—

As we return by the canal steamer to Inverness, the villas and shops, the hotels and railway stations promise no more than any other modern town to archæologist or interpreter. There seem no ancient buildings of interest, few modern ones of merit, yet on a second survey we had seen no small modern town in Scotland, hardly indeed in Britain or elsewhere, of more ambitiously monumental character. A modern castle crowns the hill, a modern cathedral stands by the river, and the towers and spires of new churches rise every here and there. Besides the weak romanticisms and conventionalities of all these, the business quarters are crowded with costly Philistinisms which would be the pride of many a larger town. In the centre of the town we have a showy Town House and fountain, the latter built over the prehistoric palladium of the borough, that fountain stone, "Clach-na-cuddain," which is not only the familiar fetish and watchword of Invernessians at home and abroad, but gives the unnoticed keynote of the town's architecture too. From minor megalith to minor Victorian architecture indeed is not an unmixed art progress; but this "Capital of the Highlands" has still to become a capital; despite latent Highland elements, its realised ideals as yet are little more than those of the Scottish market burgh and the English garrison town.

Yet as the old language comes back to the dying, and as it is with our fathers we would sleep when dead, so the undeveloped and vulgarised megalithic city of the living is overlooked by the truer and nobler megalithic city of the dead—the Hill of Tomnahurich, crowded with cross and obelisk from base to wooded crown. Here the ancient and latent art spirit is more developed, more emancipated, and so gives us one of the most characteristic, and in general effect one of the most beautiful cemeteries of Western Europe.

At this hill-foot again we found childhood at play; this time a group of merry boys, who, out of the rich variety of northern games, which we were learning to decipher as survivals of past culture-phases, had fitly gone back to the megalithic game of summer, as curling is obviously of winter—putting the stone. As the girl in her silence, as the mourners in their sighing, so now the boys in their laughter. We are wont to say that only animals have instinct, and that man acts only by reason. Is there not sometimes a word to say for the opposite?

We are wont to receive and express our emotions for the most part audibly through music or words or tones, but the emotion of architecture is latent in us still; eye and hand can surely feel as well as tongue and ear. Emotion plays not with strings or pipes only, but with things more massive and enduring also; to her Amphion-lute the very rocks range into order as sand grains ripple to the violin bow, and to her listening ear the Memnon statues sing. We speak of the rude stone ages as if they were ages of rude men, but how much is this because our tools, the machines, have mastered us, have dulled us to match their own finish? For elemental man, elemental feeling, elemental expression also; so youth, rejoicing in its strength, will ever toss the rugged stone, sorrow ever upheave her rude memorial. To feel the full depth of this ever primeval art, some modern instances must come home to us, and here by Inverness is the spot of all Scotland. On Culloden Moor there lies a gloom deeper than that of the Jacobite chronicles, a silence sadder than the songs; to these poor proud stones of the clans, landmarks of death and defeat, our heart-strings thrill as on no other stricken field.

THE OLDEST HOUSE IN GLASGOW.

A CORRESPONDENT of the *Glasgow Herald* writes:—
The advance of the modern building spirit in our city, as well as elsewhere, has a tendency to do away with all links with the past. Only the other day it was debated in Council whether the Tron Church would not be better removed. In our reforming haste it is possible that mistakes may be made that will be deplored by succeeding generations of citizens. For instance, we have still one of the ancient manses connected with the cathedral before the Reformation. This building, mentioned in M'Ure's history by the name of "Provan's Lordship," stands across the street from the north end of

Barony Church, in Cathedral Square. The back of this house is toward the Square, and this aspect of it is presented in Stuart's "Views of Glasgow," perhaps to include the little building leaning against it, which is said to have been the home of the public executioner. The original front, or present back, has three corbie-step gables, small windows and doorway, and bears the date 1070 on the eave's stone at the south-west corner. It is since the last of the local histories was written that the date was discovered, and it is a puzzle for antiquaries. In connection with this house and another of the old vicarages or manses, since removed from Rottenrow, Stuart says:—"Many will find a difficulty in believing that these houses can belong to so distant an era as that of Bishop Cameron, but the fact cannot be questioned, although they bear at the present day but few traces of the actual aspect which was theirs, owing to repairs, alterations," &c. In a petition to Parliament in 1587 from the inhabitants of Glasgow it was stated that before the "Reformation of Religion" the city was "uphelden" by the vicars and other clergy, but is now ruinous and for the most part "altogether decayit," and about that time there is no doubt that some effort was made to preserve the "grite and sumptuous buildings of grite antiquitie" that formerly belonged to the Roman Catholic prebendaries. It is possible that Provan's Lordship was originally built half-way up with stone, with outside stairs and a projecting superstructure of timber, and that in reconstructing it the date 1070 may have been put on the eave's stone as an approximation of the actual time of its erection. If it was not the first built of the vicarages, it certainly held what might be called the premier position, nearest to the great west door of the cathedral, the principal entrance of the Bishop's Palace and the Stable Green Port, in ancient times the chief gate of the city. The building itself is a marvel of strength and solidity, the interior dividing walls being 3 feet thick, the same thickness as the outer walls. The story of this house from local histories and tradition is interesting, although some parts of it are open to question. It is said to have been the manse of the celebrated William Turnbull, Bishop of Glasgow and Lord of Provan, who founded the University. In this house Cardinal Beaton is supposed to have stored the ancient documents of the cathedral, the gold image of Christ, the twelve silver images of the apostles, and other treasures which he took with him when he fled to France. There also Queen Mary may have stayed with her attendants during the sickness of Darnley in January 1567. It is unreasonable to think that Lord Darnley stayed anywhere but in the Darnley Cottage, the property of his father, and it is not improbable that the queen stayed during his convalescence in the next house to it, which was Provan's Lordship. Mary's preference for such houses as temporary residences is well known. At another period of its history it was used as the city prison during the erection of the second Tolbooth. To come down to our own time, it is now some thirty years since the first attempt was made by the City Improvement Trust to acquire it, for the purpose of its demolition, to make way for a new building, and since then it has several times been under consideration for the same purpose. The attics and cellars are closed up as insanitary. It would be a great pity to have this house destroyed for the following reasons:—

1. It is not insanitary. The tenants are respectable people and the place is kept in good order.
2. It is now closed in on three sides by new buildings, with Cathedral Square in front, and "open space-making" cannot be used as an argument for its destruction.
3. It is the last of the vicarages connected with the old chapter, and may be the most ancient inhabited house in Scotland to-day.

The current *Blackwood* contains a "Reminiscence of Tennyson" by William Knight, and in it the poet is quoted as saying that he "bemoaned the loss of all old things, old trees, old historic places, old creatures of the forest and of the air." Very little of this spirit seems now to prevail among our citizens. Did the men who wrote to the *Herald* in the early '50's about Glasgow, past and present, leave no like-minded documents? Is it asking too much that an archæological society be formed to investigate our fast disappearing old buildings, some of which are surely worth preserving?

Mr. J. Dalrymple Duncan writes:—

Your correspondent "T. W. L." is in error in supposing that the old house in Cathedral Square standing at the corner of Macleod Street is "one of the ancient manses connected with the cathedral before the Reformation." These manses were erected during the episcopate of Bishop John Cameron (1426-46), and if it could be shown that the building were one of them it would be of the utmost value and interest as a specimen of the Domestic architecture of Glasgow in the fifteenth century. But it can be readily demonstrated that it has no claim to this distinction. Even a casual glance at its architectural features will satisfy anyone capable of forming a judgment on the point that these are characteristic of a considerably

later period than the fifteenth century. Some years ago I had occasion, in writing a notice of the house for the Glasgow Regality Club, to make careful inquiries into the probable age of the building, and at that time I inspected it along with Mr. John Honeyman, who, I need scarcely say, is well qualified from his wide antiquarian and architectural knowledge to speak with authority on a question of the kind. He gave it as his opinion that the edifice, so far from being a relic of the fifteenth century, was erected during the course of the seventeenth, and most probably was not older than about 1650, basing his judgment specially on the entire absence of the Gothic feeling which is noticeable in the domestic architecture of the fifteenth century. The lintel of the principal doorway, although at some time or other it has been hollowed out so as to show an elliptical form, was originally perfectly square across, and was, like the jambs, moulded in a style common during the latter half of the seventeenth century, and the building throughout exhibited none of the preference for delicate details or mullioned windows which would undoubtedly have characterised the work of a fifteenth-century architect. From his inspection of the interior arrangements, Mr. Honeyman formed the opinion by the appearance of some of the doorways on the different storeys and the existence of thick inner walls round the staircase that the edifice had originally been built as a tenement for occupation by several families, and could not by any possibility have been a prebendal manse. I made a careful examination of the title of the property, and this tended strongly to confirm Mr. Honeyman's view. The earliest writ I was able to examine was an instrument of sasine in favour of John Trumbill, "Incola, Glasgu," and Marion Finniesone, his wife, in conjunct fee and liferent, recorded in the Particular Register of Sasines on November 3, 1642. The description of the subjects ran as follows:—"Toto et integro illo tenemento terrae jacen-intra civitatem Glasguen, occidentali latere regia via ejusdem in illa parte qua itur a porta nuncupat. Stabillgreen port ad Hospitale Sancti Nicholas." John Trumbill, John Corss, John Baird, jun., Catherine Gray and others are mentioned as occupants of the house. It will thus be seen that as far back as 1642 the house is called a tenement, and is described as occupied by a considerable number of tenants. The belief that the building was a prebendal manse arose from a statement of M'Ure's that the manse of the Prebendary of Balernock, or, as he was called, the "Lord Provan," "was at the large house near the Stablegreen port that now belongs to Mr. Bryson of Neilsland." Now, the old house in Cathedral Square at the time M'Ure wrote did belong to John Bryson of Neilsland, whence it has been somewhat too hastily assumed that it was the manse in question. But it will be observed M'Ure (who, moreover, was writing in 1736, when, even according to Mr. Honeyman's theory, the edifice was not far from a century old) does not say that Mr. Bryson's house was the manse, and his statement may be quite fairly taken to mean that the former was at or on the site of the Prebendary of Balernock's residence.

Most of the manses fell into decay and disrepair very soon after the Reformation. Some of them were included among the "sumptuous buildings of grite antiquitie," whose decay formed the burden of the petition to Parliament in 1587 mentioned by your correspondent. The animosity of the Reformers against the former dwellings of the Romish ecclesiastics was specially bitter, and when we recall the scant respect with which the cathedral itself was treated, it is only natural we should expect to find that the manses of the prebendaries were destroyed and treated by the citizens as convenient quarries and storehouses of building material. It is besides an extraordinary circumstance that, if the house in Cathedral Square was a manse, no mention of its former dignified condition should occur either in the titles of the ground on which it stands or those of the adjoining subjects. I could add other arguments, but I think I have said enough to show that the theory of the ecclesiastical origin of the edifice in the fifteenth century cannot be maintained. I should like to know your correspondent's authority for the statement that it was used at one time as a town prison.

While, however, I differ from his estimate of the antiquity of the building, I quite agree with him that an effort should be made to prevent the disappearance of an old landmark which, while far from being "the most ancient inhabited house in Scotland," must be one of the oldest pieces of domestic architecture in Glasgow which the ravages of time and the vandalism of past generations have spared to us.

A vast concourse of people assembled on Sunday, the 15th inst., to assist at the inauguration by the burgomaster of the monumental fountain erected on the Place de Brouckère, Brussels, to the memory of Jules Anspach, who became burgomaster in 1854, and to whose memorable administration the Belgian capital owes so much.

STRENGTH OF COLUMNS.

At the meeting of the British Association on Friday a paper was read by Mr. Gaetano Lanza, in which he showed that an attempt to compute the strength of any given column by the various rules and formulæ commonly found in different handbooks and books written by so-called authorities would speedily reveal considerable discrepancies, not only in the formulæ, but also in the results. Hence it became a matter of importance to make a careful study of the tests that have been made under practical conditions on columns of such sizes and proportions as are used in construction. A summary was therefore given of the principal experiments that have been made of columns of practical sizes. The greater part of the tests contained in the list were made on the United States testing machine of 800,000 lb. capacity, located at the arsenal at Watertown, Massachusetts. The details of these tests are published in special yearly reports issued by the Ordnance Department of the United States Government. Diagrams were presented showing (1) the results of the tests of cast-iron mill columns; (2) the results of the tests of wrought-iron bridge columns, and also empirical formulæ representing in each case the righthand portion of the curve, which is concave upwards; (3) the results of tests of timber columns. A perusal of all the diagrams shows that, whenever the load on a column is so applied that its resultant acts along the axis of the column, the breaking load per square inch of sectional area is practically constant up to a certain ratio of length to radius of gyration, which in wrought-iron bridge columns varies from 60 to 80, and in a corresponding way in timber columns. For higher values of the ratio of length to radius of gyration the breaking strength per square inch decreases, and the law of decrease can only be expressed empirically in each case. When, on the other hand, the load on the column is eccentric, this must be taken into account in our calculations, and the greatest fibre stress should always be computed by adding the direct stress per square inch to the greatest fibre stress arising from the bending moment due to the eccentricity of the load; and the column should then be so proportioned that the total greatest fibre stress shall not exceed a certain allowable fibre stress, which last must be a sufficiently small fraction of the breaking strength per square inch corresponding to the ratio of length to radius of gyration of the column. In the paper the results of the tests and the modes of computation, both for central and for eccentric loads, were treated in detail, and a discussion was given of the theories and formulæ commonly found in the handbooks which are, for the most part, based on the results of Hodgkinson's tests on small samples. Fuller attention was also called to the disagreement of these latter with the facts.

NEWCASTLE INFIRMARY COMPETITION.

THE competition for the new Royal Infirmary, Newcastle, is limited to thirteen architects, who are requested to send in designs for an infirmary containing 400 beds, complete in every respect and standing on the site a plan of which is furnished to the competitors. It may be necessary to retain for the present the part of the hospital known as the Dobson wing, containing about 146 beds; but the plans must provide for the eventual removal of this wing and its replacement by equivalent accommodation corresponding with the rest of the hospital, and must show how it is to be utilised in the meantime so far as its ward arrangements are concerned. It will be necessary to construct the new building step by step, and so as at all times, if possible, to maintain during the construction not less than the present number of 270 patients' beds, and the necessary accommodation for the working staff at present residing in the hospital. The accommodation for nurses, as required in the schedule, though it may be necessary to place it under the same roof as the rest of the building, must be, with the exception of the dining halls and ward sisters' rooms, separated from the working part of the hospital. Special care must be taken to preserve as much open space as possible between the buildings, and to arrange the pavilions so that the intermediate space lies, for the most, open to the south-east. The principal large wards must be built upon the pavilion system, each bed having a window on either hand. The proposed system of drainage (for surface-water and for water from lifts, as well as sewage) must be shown on a plan, with gullies, traps, inspection shafts and ventilators. The sum at the disposal of the committee for the new building, exclusive of that part which shall eventually be substituted for the west wing, is, up to the present time, 100,000*l*. An estimate must be given of the price per cubic foot at which the designer estimates his building and the entire cost so arrived at. To the author of the design which in the opinion of the committee and assessor is most worthy of it will be awarded the work of carrying his design into execution at the usual commission of 5 per cent. This 5 per cent. commission shall be in payment in full for all services usually rendered by architects, *i.e.* all plans, specifica-

tions, estimates, detail drawings, contractors' working drawings, superintendence, attendance and other expenses, and all other matters and things connected with the erection and completion of the building. To the authors of the three designs which in the opinion of the committee and assessor are next in order of merit will be awarded the respective premiums of 150%, 100% and 50%. The committee reserve to themselves the right to adopt any feature from any of the premiated designs. No distinguishing mark, motto or device is to be put on the drawings, description, statement, envelope or case by the competing architects or their agents. The designs will be submitted to Mr. Alfred Waterhouse, R.A., who will advise the committee in their selection.

A schedule accompanies the instructions as to the requirements of the new infirmary, on the understanding that the Dobson wing is not to be retained as a permanent part of the new infirmary. The following are extracts from it:—400 beds, 180 medical and 220 surgical. The medical department to consist of four large wards of twenty-two beds each, two wards of four beds, and four wards each of one bed for males, 100; one ward of ten beds, with two separation wards of one bed each, for children, 12; two wards of twenty-four beds each, with each one separation ward of one bed for females, 50; two wards of eight beds each, with each one separation ward of one bed for females, 18; total medical, 180. The surgical department to consist of four wards of twenty-four beds each, with each one separation ward of one bed, for males, 100; four wards of four beds each, for males, 16; two wards of two beds each, for males, 4; two wards of twenty-four beds each, with each two separation wards of one bed for females, 52; two wards of ten beds, with each a separation ward of one bed for females, 22; six wards of one bed each, for females, 6; two wards of eight beds each, with each two separation wards of one bed each, for children, 20; total surgical, 220. Each large ward or group of small wards to be provided with a sisters sitting-room, a duty-room or ward kitchen, a room for patients' clothes, a storeroom for bread, milk, &c., lavatories, foul sinks, urinals, and w.c.'s in proportion, a bathroom (but in medical large wards two bathrooms), a closet for ward linen, earthenware, &c., and a patients' dayroom for each flat. A room for photography. Reasonable accommodation for the examination of secretions, &c., suitable also for electrical treatment of patients. An office for receiving and passing applicants. A large waiting-hall for patients, provided with benches that admit of arrangements into groups for male and female surgical and medical patients, convenient for the respective consulting rooms. The hall is also to be available as a recreation room or room for large meetings. A small operating room, with lavatory basins, sinks, &c. Operating theatres, easily accessible by lift—one large, to accommodate sixty students, to have the following annexes: anæsthetic room, waiting-room with bed, sterilising room, microscopic room; second small, near the female surgical wards, to have waiting-room and anæsthetic room. Lecture theatre to hold 100 students. Library, the size of the present library and staff-room together (57 feet by 20 feet). Staff-room, with lavatory, &c. Arrangements for students:—A common room, cloak-room for 120 coats, hats, &c., cloak-room for lady students, bicycle standing room for fifty bicycles. Resident medical and surgical officers:—Senior house physician's sitting and bedroom, four sitting-rooms and eight bedrooms for house physicians and house surgeons, a sitting-room for assistant house surgeon, near the accident-room, two spare bedrooms, two bath-rooms. Mortuary, with view-room attached. Post-mortem room, communicating with mortuary with double doors. Two post-mortem tables; benches for sixty students.

The accident and reception-room department should be easily accessible by carriages from the public road; the door, if possible, protected by a porch and away from public curiosity and on a level with the outside, or at any rate without steps; a waiting-room for about thirty people, two bedrooms of two beds each for noisy or drunken patients.

The remainder of the schedule is devoted to requirements for general administration, kitchen, laundry, &c.

TESSERÆ.

Greek Influence.

THE Greek dominion over the realms of thought was as undisputed as the Roman over the realms of earth. Almost every field of literature and science the Greeks may claim as their own by the right of prior discovery. Few are the directions in which the modern explorer does not find traces of Greek settlement and occupation. Even when they did not penetrate into the interior, as in the case of Sicily, they at least colonised the coast. Even in mathematical and physical science and in mechanical arts, the rapid extension of which is the boast and glory of modern times, the Greeks took the first

steps. In all the forms of literature, in the fine arts, in the modern sciences, modern nations—counting together a population perhaps twenty times more numerous than that of Hellas and its colonies, with their manifold advantages in accumulated knowledge, increased experience and extant models—have scarcely equalled and never surpassed the unaided efforts and spontaneous developments of Greek skill and Greek genius. Time and chance, the blind workers—abetted by the no less blind workers, ignorance, barbarism and bigotry—have too often conspired to involve in one common destruction the temple and the library, the statue and the picture; and probably the extant remains of Greek literature bear no larger proportion to the whole mass than the ruins of Athens bear to the thick clustered glories which delighted the eye of Hadrian; still, enough remains to prove by an infallible test the right of Homer, Sophocles, Plato, Aristotle, Phidias, and others to rank for ever among the foremost names of time. Who, having seen, can forget, or who, not having seen, does not desire to see, those columns of Phidias, as they stand high above the modern city alone in their beauty, and white against the sky, the despair of the architect and the wonder of the world? And there are other works wrought by the Greeks of old which shall stand forth conspicuous in undiminished splendour long after the Parthenon has crumbled into dust.

Columns as Piers.

One very great advantage attending the combination of the arch with the column as its support is that it allows the openings to be considerably wider than they otherwise could be, because such intervals as would produce a poor and straggling effect in a colonnade become well proportioned and agreeable when spanned by arches. Such columnar arcades have frequently been employed by the Italians with happy effect in cortili and places of that kind, where piers of the usual kind would obstruct the view too much, and where intercolumns of the same proportions between pillars supporting a horizontal entablature would have a poor and disagreeable effect, particularly if, as is generally the case, other storeys of the building rested upon the porticoes below. In fact, ordinances composed of arches and pillars constitute the best specimens of Italian columniated architecture. That in the cortile of the Palazzo Piccolomini at Siena, the work of Francesco di Giorgio, is singularly beautiful in its distribution, remarkable for the richness of its details, and also for the variety which it presents in perspective, as may be judged from the view of it given in Grandjean and Famin's "Architecture Toscane." The interior of St. Martin's-in-the-Fields contains an example of arches upon columns, and St. Bride's, London, furnishes another, but neither is a favourable one. A more satisfactory example may be found within the loggia of the Strand portion of Somerset House, where, though the arches spring from entablatures over the columns, yet, as the latter are placed in pairs, those horizontal parts are more than mere upright blocks over the capitals. The quadrangle of the old Royal Exchange, London, had arches springing immediately from the capitals of the columns, but their breadth was excessive in proportion to the height of the latter, and their elliptical form was a great defect, and certainly did not at all contribute to beauty. All that we contend for is the principle on which the practice is founded, for as to the merits of the buildings in which it is adopted, that must, like everything else in architecture, depend upon the taste shown in the particular application of it, which may be exceedingly good or altogether the reverse.

Memorial Brasses.

In the time of Herodotus edicts and public records were sometimes inscribed on brass tablets—a striking instance of which occurs in the preservation down to the present time of the will and acts of the Emperor Augustus. In the eighth century by a law of Kenneth, king of Scotland, it was enjoined that a cross should be put on every gravestone (*i.e.* coffin lid); and this appears to have been done in three ways—(1) by the use of incised lines drawn round the object; (2) by producing the form in low relief; and (3) by a wholly excised figure. The use of sepulchral brasses appears to have originated with the general revival of art in the thirteenth century. One of the earliest specimens is that of Sir Roger de Trompington, who died in 1289. The brasses of the fourteenth and fifteenth centuries contain, besides the effigies of warriors, churchmen, ladies and civilians, many examples of beautiful decoration—derived from the architectural practice of the time. Different combinations of the letters I.H.S., composing the sacred monogram, appear in the brasses of the fifteenth and beginning of the sixteenth century. In the sixteenth century, at the time of the Reformation, these sacred monuments appear to have become obnoxious and were accordingly swept out of the churches with an unsparing hand, comparatively few having escaped destruction. It is desirable for the nation to possess a complete collection of the rubbings of the brasses which have survived as illustrative of the costume and history of bygone times, and the propriety of such a collection being deposited in the British Museum.

NOTES AND COMMENTS.

AMERICAN manufacturers appear to be eager to supply the British market with the most delicate tools, and one firm is likely to be able to claim the position of tool-makers to the British Association. At the meeting of the Association last year a special committee in Liverpool reported that sufficiently accurate gauges of the Association screw threads were not generally procurable. Methods were described of exactly measuring male threads, and a form of gauge for male threads was proposed which they anticipated could be more accurately produced and more easily verified than the forms in common use. In continuation of this course the committee have been in correspondence with some of the principal tool-makers in England and America, with a view to procuring accurate gauges of the different screw threads of the British Association system constructed on the lines indicated in their last report. It was found that a company in Hartford, Connecticut, had already begun to construct tools for these threads, and are giving close attention to their accurate production. The company have kindly promised to communicate with the committee of the Association as soon as the work is sufficiently advanced to allow them to make proposals for the supply of the gauges, and the committee hope that exact gauges will soon be obtainable from this source.

STUDENTS of geology who are no longer young may remember the interest excited when they first read of the experiments of GREGORY WATT on basalt. He melted some blocks. Those which were cooled quickly formed a sort of glass resembling slag. Those which were cooled more slowly assumed first the form of globules, which increased in size and became balls of equal sizes. A layer of the balls was subjected to pressure in every direction, and it was found that every ball became squeezed into a regular hexagon. It was concluded that the columnar structure of basalt was due to immense forces operating similarly. Experiments no less interesting have been conducted by Messrs. ADAMS and NICHOLSON in McGill University, and some of the results were brought under the notice of the meeting of the British Association at Toronto. The object was to ascertain whether it is possible, by subjecting rocks artificially to pressure under the conditions which obtain in the deeper parts of the earth's crust, to produce in them the deformation and cataclastic structures exhibited by the folded rocks of the interior of mountain ranges or of the older formations of the earth. The experiments have been made chiefly with pure Carrara marble. Columns of the marble 2 centimetres and $2\frac{1}{2}$ centimetres in diameter and about 4 centimetres in length were very accurately turned and polished. Heavy wrought-iron tubes were then made, imitating the plan adopted in the construction of ordnance, by rolling long strips of Swedish iron around a bar of soft wrought-iron, and welding the strips to the bar as they were rolled around it. The core of soft iron composing the bar was then drilled out, leaving a tube of welded Swedish iron 6 millimetres thick, so constructed that the fibres of the iron run around the tube, instead of being parallel to its length. This tube was then very accurately fitted on to the column of marble. This was accomplished by giving a very slight taper to both the column and the interior of the tube, and so arranging it that the marble would pass only about halfway into the tube when cold. The tube was then expanded by heating, so as to allow the marble to pass completely into it, and leave about 3 centimetres of the tube free at either end. On allowing the tube to cool a perfect contact between the iron and marble was obtained, and it was no longer possible to withdraw the latter. Into either end of the tube containing the small column an accurately fitting sliding steel plug was inserted, and by means of these the marble was submitted to a pressure far above that which would be sufficient to crush it if not so enclosed. Under the pressure, which was applied gradually and in some cases continued for several weeks, the tube was found to slowly bulge until a very marked enlargement of the portion surrounding the marble had taken place. The tube was then cut through longitudinally by means of a milling machine along two lines opposite one another. The marble within, however, was still firm, and held the respective sides of the iron tube, now completely

separated, so tightly together that it was impossible without mechanical aids to tear these apart. By means of a wedge, however, they could be separated, splitting the marble through longitudinally. The column in one experiment was reduced from 40 millimetres to 21 millimetres in height. The deformed marble differs from the original rock in having a dead white colour, the glistening cleavage faces of calcite being no longer visible, and although not so hard as the original rock, it is still firm and compact, and especially so when its deformation has been carried out very slowly. The experiments show that limestone, even when dry and at ordinary temperatures, does possess a certain degree of plasticity, and can be made to "flow," the movements set up developing many structures which are characteristic of rocks which have been squeezed or folded in the deeper portions of our earth's crust. It is to be hoped Messrs. ADAMS and NICHOLSON will continue their experiments, for in addition to their geological interest they suggest that much remains to be known about the strength of marble under constant pressure, and, it may be, about other materials also.

THE Eighth Chamber, or police court, in Paris has given judgment in the charge brought against Le Baron de MACKAU and the two men who worked the cinematograph, as the alleged authors of the catastrophe of the charity bazaar in the Rue Jean Goujon. The Baron was fined 500 francs and the others 200 and 300 francs, with eight and twelve months' imprisonment respectively, but all three escaped in virtue of the Béringer law, which favours first offences. There was no doubt the fire originated with the photographic apparatus. The Baron was charged with a general neglect of precautions. It appears that the structure was used a few weeks before for the representation of a sort of Passion play. On that occasion firemen were on the spot. For the charity bazaar some of the doors were closed, and a cooking apparatus was introduced. The photographic apparatus was also placed in a wooden enclosure covered with "carton bitumé" and hung with light drapery. M. BUNEL, an architect, has calculated that on the day of the catastrophe there were four persons per square metre in the assembly. There were three doors, he said, which would have sufficed if the people had retained their self-control. It was found that nearly eighty victims had been deceived by supposing that some painted doors were realities, and they were found in a heap before them. M. BUNEL expressed the opinion that the "carton bitumé" was less dangerous than a covering in zinc. Another fact which came out in the evidence was that the prefecture of police insisted on a preservative wash being applied to the decorations to make them fireproof, but it was omitted from the awning or covering of the bazaar. The defendants have appealed, and it is by no means clear what law or regulation they offended against. Officialism meddles with all things, but the bazaar was not noticed. The arrangements for the erection of a mortuary chapel on the site are not completed. A part of the ground has been purchased, but it is in contemplation to acquire the whole of the area. In that case a much larger building could be erected.

NEW PREMISES, STEELHOUSE LANE AND UPPER PRIORY, BIRMINGHAM.

THIS shop and warehouse is now being built for Mr. FELIX CHAPMAN by Messrs. SAMPSON & SONS, builders, of Birmingham. The premises comprise shop on the ground floor, show-room on the first floor, and warehouse in basement and on the upper floors, with a manager's house over the gateway.

The elevations are of red brick and buff and red terracotta, and the roofs will be of red pantiles.

The architects are Messrs. ESSEX, NICOL & GOODMAN, of Birmingham.

ARCHÆOLOGY AND PHYSICAL SCIENCE.*

IT is no doubt hard to define the exact limits which are to be assigned to archæology as a science, and archæology as a branch of history and Belles-Lettres. A distinction is frequently drawn between science on the one hand and knowledge or learning on the other, but translate the terms into Latin and the distinction at once disappears. In illustration of this I need only cite Bacon's great work on the "Advancement of Learning," which was, with his own aid, translated into Latin under the title "De Augmentis Scientiarum."

It must, however, be acknowledged that a distinction does exist between archæology proper, and what, for want of a better word, may be termed antiquarianism. It may be interesting to know the internal arrangements of a Dominican convent in the Middle Ages; to distinguish between the different mouldings characteristic of the principal styles of Gothic architecture; to determine whether an English coin bearing the name of Henry was struck under Henry II., Richard, John, or Henry III., or to decide whether some given edifice was erected in Roman, Saxon, or Norman times. But the power to do this, though involving no small degree of detailed knowledge and some acquaintance with scientific methods, can hardly entitle its possessors to be enrolled among the votaries of science.

A familiarity with all the details of Greek and Roman mythology and culture must be regarded as a literary rather than a scientific qualification, and yet when among the records of classical times we come upon traces of manners and customs which have survived for generations and which seem to throw some rays of light upon the dim past, when history and writing were unknown, we are, I think, approaching the boundaries of scientific archæology.

Every reader of Virgil knows that the Greeks were not merely orators, but that with a pair of compasses they could describe the movements of the heavens and fix the rising of the stars; but when by modern astronomy we can determine the heliacal rising of some well-known star, with which the worship in some given ancient temple is known to have been connected and can fix its position on the horizon at some particular spot, say, three thousand years ago, and then find that the axis of the temple is directed exactly towards that spot, we have some trustworthy scientific evidence that the temple in question must have been erected at a date approximately 1,100 years B.C. If on or close to the same site we find that more than one temple was erected, each having a different orientation, these variations, following as they may fairly be presumed to do the changing position of the rising of the dominant star, will also afford a guide as to the chronological order of the different foundations. The researches of Mr. Penrose seem to show that in certain Greek temples, of which the date of foundation is known from history, the actual orientation corresponds with that theoretically deduced from astronomical data.

Sir J. Norman Lockyer has shown that what holds good for Greek temples applies to many of far earlier date in Egypt, though up to the present time hardly a sufficient number of accurate observations have been made to justify us in foreseeing all the instructive results that may be expected to arise from astronomy coming to the aid of archæology.

The intimate connection of archæology with other sciences is in no case so evident as with respect to geology, for when considering subjects such as those I shall presently discuss, it is almost impossible to say where the one science ends and the other begins.

By the application of geological methods many archæological questions relating even to subjects on the borders of the historical period have been satisfactorily solved. A careful examination of the limits of the area over which its smaller coins are found has led to the position of many an ancient Greek city being accurately ascertained; while in England it has only been by treating the coins of the Ancient Britons, belonging to a period before the Roman occupation, as if they were actual fossils, that the territories under the dominion of the various kings and princes who struck them have been approximately determined. In arranging the chronological sequence of these coins, the evolution of their types—a process almost as remarkable, and certainly as well defined, as any to be found in nature—has served as an efficient guide. I may venture to add that the results obtained from the study of the morphology of this series of coins were published ten years before the appearance of Darwin's great work on the "Origin of Species."

When we come to the consideration of the relics of the Early Iron and Bronze Ages, the aid of chemistry has of necessity to be invoked. By its means we are able to determine whether the iron of a tool or weapon is of meteoritic or volcanic origin or has been reduced from iron-ore, in which case considerable knowledge of metallurgy would be involved on the part of those who made it. With bronze antiquities the nature and extent of the alloys combined with the copper may

throw light not only on their chronological position, but on the sources whence the copper, tin and other metals of which they consist were originally derived. I am not aware of there being sufficient differences in the analyses of the native copper from different localities in the region in which we are assembled for Canadian archæologists to fix the sources from which the metal was obtained which was used in the manufacture of the ancient tools and weapons of copper that are occasionally discovered in this part of the globe.

Like chemistry, mineralogy and petrology may be called to the assistance of archæology in determining the nature and source of the rocks of which ancient stone implements are made; and, thanks to researches of the followers of those sciences, the old view that all such implements formed of jade and found in Europe must of necessity have been fashioned from material imported from Asia can no longer be maintained. In one respect the archæologist differs in opinion from the mineralogist, namely, as to the propriety of chipping off fragments from perfect and highly-finished specimens for the purpose of submitting them to microscopic examination.

I have hitherto been speaking of the aid that other sciences can afford to archæology when dealing with questions that come almost, if not quite, within the fringe of history, and belong to times when the surface of our earth presented much the same configuration as regards the distribution of land and water, and hill and valley, as it does at present, and when, in all probability, the climate was much the same as it now is. When, however, we come to discuss that remote age in which we find the earliest traces that are at present known of man's appearance upon earth, the aid of geology and palæontology becomes absolutely imperative.

The changes in the surface configuration and in the extent of the land, especially in a country like Britain, as well as the modifications of the fauna and flora since those days, have been such that the archæologist pure and simple is incompetent to deal with them, and he must either himself undertake the study of these other sciences or call experts in them to his assistance. The evidence that man had already appeared upon the earth is afforded by stone implements wrought by his hands, and it falls strictly within the province of the archæologist to judge whether given specimens were so wrought or not; it rests with the geologist to determine their stratigraphical or chronological position, while the palæontologist can pronounce upon the age and character of the associated fauna and flora.

If left to himself the archæologist seems too prone to build up theories founded upon form alone, irrespective of geological conditions. The geologist, unaccustomed to archæological details, may readily fail to see the difference between the results of the operations of nature and those of art, and may be liable to trace the effects of man's handiwork in the chipping, bruising and wearing which in all ages result from natural forces; but the united labours of the two, checked by those of the palæontologist, cannot do otherwise than lead towards sound conclusions.

It will perhaps be expected of me that I should on the present occasion bring under review the state of our present knowledge with regard to the antiquity of man; and probably no fitter place could be found for the discussion of such a topic than the adopted home of my venerated friend, the late Sir Daniel Wilson, who first introduced the word "prehistoric" into the English language.

Some among us may be able to call to mind the excitement, not only among men of science, but among the general public, when, in 1859, the discoveries of M. Boucher de Perthes and Dr. Rigollot in the gravels of the valley of the Somme, at Abbeville and Amiens, were confirmed by the investigations of the late Sir Joseph Prestwich, myself and others, and the co-existence of man with the extinct animals of the quaternary fauna, such as the mammoth and woolly-haired rhinoceros, was first virtually established. It was at the same time pointed out that these relics belonged to a far earlier date than the ordinary stone weapons found upon the surface, which usually showed signs of grinding or polishing, and that in fact there were two Stone Ages in Britain. To these the terms neolithic and palæolithic were subsequently applied by Sir John Lubbock.

The excitement was not less when, at the meeting of this Association at Aberdeen in the autumn of that year, Sir Charles Lyell, in the presence of the Prince Consort, called attention to the discoveries in the valley of the Somme, the site of which he had himself visited, and to the vast lapse of time indicated by the position of the implements in drift-deposits 100 feet above the existing river.

The conclusions forced upon those who examined the facts on the spot did not receive immediate acceptance by all who were interested in geology and archæology, and fierce were the controversies on the subject that were carried on both in the newspapers and before various learned societies.

It is at the same time instructive and amusing to look back on the discussions of those days. While one class of objectors accounted for the configuration of the flint implements from the gravels by some unknown chemical agency, by the violent

* Presidential address by Sir John Evans, K.C.B., D.C.L., LL.D., &c., delivered at the opening meeting of the British Association for the Advancement of Science in Toronto, on August 12.

and continued gyratory action of water, by fracture resulting from pressure, by rapid cooling when hot or by rapid heating when cold, or even regarded them as aberrant forms of fossil fishes, there were others who, when compelled to acknowledge that the implements were the work of men's hands, attempted to impugn and set aside the evidence as to the circumstances under which they had been discovered. In doing this they adopted the view that the worked flints had either been introduced into the containing beds at a comparatively recent date, or if they actually formed constituent parts of the gravel then that this was a mere modern alluvium resulting from floods at no very remote period.

In the course of a few years the main stream of scientific thought left this controversy behind, though a tendency to cut down the lapse of time necessary for all the changes that have taken place in the configuration of the surface of the earth and in the character of its occupants since the time of the Palæolithic gravels, still survives in the inmost recesses of the hearts of not a few observers.

In his address to this Association at the Bath meeting of 1864, Sir Charles Lyell struck so true a note that I am tempted to reproduce the paragraph to which I refer:—

"When speculations on the long series of events which occurred in the glacial and post-glacial periods are indulged in, the imagination is apt to take alarm at the immensity of the time required to interpret the monuments of these ages, all referable to the era of existing species. In order to abridge the number of centuries which would otherwise be indispensable, a disposition is shown by many to magnify the rate of change in prehistoric times by investing the causes which have modified the animate and inanimate world with extraordinary and excessive energy. It is related of a great Irish orator of our day that when he was about to contribute somewhat parsimoniously towards a public charity, he was persuaded by a friend to make a more liberal donation. In doing so he apologised for his first apparent want of generosity by saying that his early life had been a constant struggle with scanty means, and that 'they who are born to affluence cannot easily imagine how long a time it takes to get the chill of poverty out of one's bones.' In like manner we of the living generation, when called upon to make grants of thousands of centuries in order to explain the events of what is called the modern period, shrink naturally at first from making what seems so lavish an expenditure of past time. Throughout our early education we have been accustomed to such strict economy in all that relates to the chronology of the earth and its inhabitants in remote ages, so fettered have we been by old traditional beliefs that even when our reason is convinced and we are persuaded that we ought to make more liberal grants of time to the geologist, we feel how hard it is to get the chill of poverty out of our bones."

Many, however, have at the present day got over this feeling, and of late years the general tendency of those engaged upon the question of the antiquity of the human race has been in the direction of seeking for evidence by which the existence of man upon the earth could be carried back to a date earlier than that of the Quaternary gravels.

There is little doubt that such evidence will eventually be forthcoming, but, judging from all probability, it is not in Northern Europe that the cradle of the human race will eventually be discovered, but in some part of the world more favoured by a tropical climate, where abundant means of subsistence could be procured, and where the necessity for warm clothing did not exist.

Before entering into speculations on this subject or attempting to lay down the limits within which we may safely accept recent discoveries as firmly established, it will be well to glance at some of the cases in which implements are stated to have been found under circumstances which raise a presumption of the existence of man in pre-Glacial, Pliocene or even Miocene times.

Flint implements of ordinary Palæolithic type have, for instance, been recorded as found in the eastern counties of England, in beds beneath the chalky boulder clay; but on careful examination the geological evidence has not to my mind proved satisfactory, nor has it, I believe, been generally accepted. Moreover, the archaeological difficulty that man, at two such remote epochs as the pre-Glacial and the post-Glacial, even if the term Glacial be limited to the chalky boulder clay, should have manufactured implements so identical in character that they cannot be distinguished apart, seems to have been entirely ignored.

Within the last few months we have had the report of worked flints having been discovered in the late Pliocene forest bed of Norfolk, but in that instance the signs of human workmanship upon the flints are by no means apparent to all observers.

But such an antiquity as that of the forest bed is as nothing when compared with that which would be implied by the discoveries of the work of men's hands in the Pliocene and Miocene beds of England, France, Italy and Portugal, which have been accepted by some geologists. There is one feature

in these cases which has hardly received due attention, and that is the isolated character of the reputed discoveries. Had man, for instance, been present in Britain during the Crag period, it would be strange indeed if the sole traces of his existence that he left were a perforated tooth of a large shark, the sawn rib of a manatee and a beaming full face carved on the shell of a pectunculus.

In an address to the Anthropological Section at the Leeds meeting of this Association in 1890 I dealt somewhat fully with these supposed discoveries of the remains of human art in beds of Tertiary date, and I need not here go further into the question. Suffice it to say that I see no reason why the verdict of "Not proven" at which I then arrived should be reversed.

In the case of a more recent discovery in Upper Burma in beds at first pronounced to be Upper Miocene, but subsequently "definitely ascertained to be Pliocene," some of the flints are of purely natural and not artificial origin, so that two questions arise, first, Were the fossil remains associated with the worked flints or with those of natural forms? and second, Were they actually found in the bed to which they have been assigned, or did they merely lie together on the surface?

Even the *Pithecanthropus erectus* of Dr. Eugène Dubois from Java meets with some incredulous objectors from both the physiological and the geological sides. From the point of view of the latter the difficulty lies in determining the exact age of what are apparently alluvial beds in the bottom of a river valley.

When we return to Palæolithic man it is satisfactory to feel that we are treading on comparatively secure ground, and that the discoveries of the last forty years in Britain alone enable us to a great extent to reconstitute his history. We may not know the exact geological period when first he settled in the British area, but we have good evidence that he occupied it at a time when the configuration of the surface was entirely different from what it is at present, when the river valleys had not been cut down to anything like their existing depth, when the fauna of the country was of a totally different character from that of the present day, when the extension of the southern part of the island seaward was in places such that the land was continuous with that of the Continent, and when in all probability a far more rainy climate prevailed. We have proofs of the occupation of the country by man during the long lapse of time that was necessary for the excavation of the river valleys. We have found the old floors on which his habitations were fixed; we have been able to trace him at work on the manufacture of flint instruments, and by building up the one upon the other the flakes struck off by the primæval workman in those remote times we have been able to reconstruct the blocks of flint which served as his material.

That the duration of the Palæolithic period must have extended over an almost incredible length of time is sufficiently proved by the fact that valleys, some miles in width and of a depth of from 100 to 150 feet, have been eroded since the deposit of the earliest implement-bearing beds. Nor is the apparent duration of this period diminished by the consideration that the floods which hollowed out the valleys were not in all probability of such frequent occurrence as to teach Palæolithic man by experience the danger of settling too near to the streams, for had he kept to the higher slopes of the valley there would have been but little chance of his implements having so constantly formed constituent parts of the gravels deposited by the floods.

The examination of British cave-deposits affords corroborative evidence of this extended duration of the Palæolithic period. In Kent's Cavern at Torquay, for instance, we find in the lowest deposit, the breccia below the red cave-earth, implements of flint and chert corresponding in all respects with those of the high level and most ancient river gravels. In the cave-earth these are scarcer, though implements occur which also have their analogues in the river deposits, but what is more remarkable, harpoons of reindeer's horn and needles of bone are present, identical in form and character with those of the caverns of the Reindeer period in the south of France, and suggestive of some bond of union or identity of descent between the early troglodytes, whose habitations were geographically so widely separated the one from the other.

In a cavern at Creswell Crags, on the confines of Derbyshire and Nottinghamshire, a bone has moreover been found engraved with a representation of parts of a horse in precisely the same style as the engraved bones of the French caves.

It is uncertain whether any of the river-drift specimens belong to so late a date as these artistic cavern-remains, but the greatly superior antiquity of even these to any Neolithic relics is testified by the thick layer of stalagmite, which had been deposited in Kent's Cavern before its occupation by men of the Neolithic and Bronze periods.

Towards the close of the period covered by the human occupation of the French caves there seems to have been a dwindling in the number of the larger animals constituting the Quaternary fauna, whereas their remains are present in abundance in the lower and therefore more recent of the valley

gravels. This circumstance may afford an argument in favour of regarding the period represented by the later French caves as a continuation of that during which the old-river gravels were deposited, and yet the great change in the fauna that has taken place since the latest of the cave deposits included in the Palæolithic period is indicative of an immense lapse of time.

How much greater must have been the time required for the more conspicuous change between the old Quaternary fauna of the river gravels and that characteristic of the Neolithic period.

As has been pointed out by Professor Boyd Dawkins, only thirty-one out of the forty-eight well-ascertained species living in the post-Glacial or River-drift period survived into pre-historic or Neolithic times. We have not, indeed, any means at command for estimating the number of centuries which such an important change indicates, but when we remember that the date of the commencement of the Neolithic or Surface Stone period is still shrouded in the mist of a dim antiquity, and that prior to that commencement the River-drift period had long come to an end, and when we further take into account the almost inconceivable ages that even under the most favourable conditions the excavation of wide and deep valleys by river action implies, the remoteness of the date at which the Palæolithic period had its beginning almost transcends our powers of imagination.

We find distinct traces of river action from 100 to 200 feet above the level of existing streams and rivers, and sometimes at a great distance from them; we observe old freshwater deposits on the slopes of valleys several miles in width; we find that long and lofty escarpments of rock have receded unknown distances since their summits were first occupied by a Palæolithic man; we see that the whole side of a wide river valley has been carried away by an invasion of the sea, which attacked and removed a barrier of chalk cliffs from 400 to 600 feet in height; we find that what was formerly an inland river has widened out into an arm of the sea, now the highway of our fleets, and that gravels which were originally deposited in the bed of some ancient river now cap isolated and lofty hills.

And yet, remote as the date of the first known occupation of Britain by man may be, it belongs to what, geologically speaking, must be regarded as a quite recent period, for we are now in a position to fix with some degree of accuracy its place on the geological scale. Thanks to investigations ably carried out at Hoxne in Suffolk, and at Hitchin in Hertfordshire, by Mr. Clement Reid, under the auspices of this Association and of the Royal Society, we know that the implement-bearing beds at those places undoubtedly belong to a time subsequent to the deposit of the great chalky boulder clay of the Eastern counties of England. It is, of course, self-evident that this vast deposit, in whatever manner it may have been formed, could not, for centuries after its deposition was complete, have presented a surface inhabitable by man. Moreover, at a distance but little farther north, beds exist which also, though at a somewhat later date, were apparently formed under glacial conditions. At Hoxne the interval between the deposit of the boulder clay and of the implement-bearing beds is distinctly proved to have witnessed at least two noteworthy changes in climate. The beds immediately reposing on the clay are characterised by the presence of alder in abundance, of hazel and yew, as well as by that of numerous flowering plants indicative of a temperate climate very different from that under which the boulder clay itself was formed. Above these beds characterised by temperate plants comes a thick and more recent series of strata, in which leaves of the dwarf Arctic willow and birch abound, and which were in all probability deposited under conditions like those of the cold regions of Siberia and North America.

At a higher level and of more recent date than these—from which they are entirely distinct—are the beds containing palæolithic implements, formed in all probability under conditions not essentially different from those of the present day. However this may be, we have now conclusive evidence that the palæolithic implements are, in the eastern counties of England, of a date long posterior to that of the great chalky boulder clay.

It may be said, and said truly, that the implements at Hoxne cannot be shown to belong to the beginning rather than to some later stage of the Palæolithic period. The changes, however, that have taken place at Hoxne in the surface configuration of the country prove that the beds containing the implements cannot belong to the close of that period.

It must, moreover, be remembered that in what are probably the earliest of the palæolithic deposits of the Eastern counties, those at the highest level, near Brandon in Norfolk, where the gravels contain the largest proportion of pebbles derived from glacial beds, some of the implements themselves have been manufactured from materials not native to the spot but brought from a distance, and derived in all probability either from the boulder clay or from some of the beds associated with it.

We must, however, take a wider view of the whole question, for it must not for a moment be supposed that there are the slightest grounds for believing that the civilisation, such as it was, of the Palæolithic period originated in the British

Isles. We find in other countries implements so identical in form and character with British specimens that they might have been manufactured by the same hands. These occur over large areas in France under similar conditions to those that prevail in England. The same forms have been discovered in the ancient river gravels of Italy, Spain and Portugal. Some few have been recorded from the north of Africa, and analogous types occur in considerable numbers in the south of that continent. On the banks of the Nile many hundreds of feet above its present level, implements of the European types have been discovered; while in Somaliland, in an ancient river valley at a great elevation above the sea, Mr. Seton-Karr has collected a large number of implements formed of flint and quartzite, which, judging from their form and character, might have been dug out of the drift deposits of the Somme or the Seine, the Thames or the ancient Solent.

In the valley of the Euphrates implements of the same kind have also been found, and again farther east in the lateritic deposits of Southern India they have been obtained in considerable numbers. It is not a little remarkable, and is at the same time highly suggestive, that a form of implement almost peculiar to Madras reappears among implements from the very ancient gravels of the Manzanares at Madrid. In the case of the African discoveries we have as yet no definite palæontological evidence by which to fix their antiquity, but in the Narbadá Valley of Western India Palæolithic implements of quartzite seem to be associated with a local fauna of Pleistocene age, comprising, like that of Europe, the elephant, hippopotamus, ox, and other mammals of species now extinct. A correlation of the two faunas with a view of ascertaining their chronological relations is beset with many difficulties, but there seems reason for accepting this Indian Pleistocene fauna as in some degree more ancient than the European.

Is this not a case in which the imagination may be fairly invoked in aid of science? May we not from these data attempt in some degree to build up and reconstruct the early history of the human family? There, in Eastern Asia, in a tropical climate, with the means of subsistence readily at hand, may we not picture to ourselves our earliest ancestors gradually developing from a lowly origin, acquiring a taste for hunting, if not indeed being driven to protect themselves from the beasts around them, and evolving the more complicated forms of tools or weapons from the simpler flakes which had previously served them as knives? May we not imagine that, when once the stage of civilisation denoted by these Palæolithic implements had been reached, the game for the hunter became scarcer, and that his life in consequence assumed a more nomad character? Then, and possibly not till then, may a series of migrations to "fresh woods and pastures new" not unnaturally have ensued, and these following the usual course of "westward towards the setting sun" might eventually lead to a Palæolithic population finding its way to the extreme borders of Western Europe, where we find such numerous traces of its presence.

How long a term of years may be involved in such a migration it is impossible to say, but that such a migration took place the phenomena seem to justify us in believing. It can hardly be supposed that the process that I have shadowed forth was reversed, and that man, having originated in North-Western Europe, in a cold climate where clothing was necessary and food scarce, subsequently migrated eastward to India and southward to the Cape of Good Hope. As yet our records of discoveries in India and Eastern Asia are but scanty; but it is there that the traces of the cradle of the human race are, in my opinion, to be sought, and possibly future discoveries may place upon a more solid foundation the visionary structure that I have ventured to erect.

It may be thought that my hypothesis does not do justice to what Sir Thomas Browne has so happily termed "that great antiquity, America." I am, however, not here immediately concerned with the important neolithic remains of all kinds with which this great continent abounds. I am now confining myself to the question of Palæolithic man and his origin, and in considering it I am not unmindful of the Trenton implements, though I must content myself by saying that the "turtle-back" form is essentially different from the majority of those on the wide dissemination of which I have been speculating, and, moreover, as many here present are aware, the circumstances of the finding of these American implements are still under careful discussion.

Leaving them out of the question for the present, it may be thought worth while to carry our speculations rather further, and to consider the relations in time between the Palæolithic and the Neolithic periods. We have seen that the stage in human civilisation denoted by the use of the ordinary forms of Palæolithic implements must have extended over a vast period of time if we have to allow for the migration of the primæval hunters from their original home, wherever it may have been in Asia or Africa, to the west of Europe, including Britain. We have seen that, during this migration, the forms of the weapons and tools made from silicious stones had become, as it were, stereotyped, and further, that during the subsequent extended

period implied by the erosion of the valleys, the modifications in the form of the implements and the changes in the fauna associated with the men who used them were but slight.

At the close of the period during which the valleys were being eroded comes that represented by the latest occupation of the caves by Palæolithic man, when both in Britain and in the south of France the reindeer was abundant; but among the stone weapons and implements of that long troglodytic phase of man's history not a single example with the edge sharpened by grinding has as yet been found. All that can safely be said is that the larger implements as well as the larger mammals had become scarcer, that greater power in chipping flint had been attained, that the arts of the engraver and the sculptor had considerably developed, and that the use of the bow had probably been discovered.

Directly we encounter the relics of the Neolithic period, often, in the case of the caves lately mentioned, separated from the earlier remains by a thick layer of underlying stalagmite, we find flint hatchets polished at the edge and on the surface, cutting at the broad and not at the narrow end, and other forms of implements associated with a fauna in all essential respects identical with that of the present day.

Were the makers of these polished weapons the direct descendants of Palæolithic ancestors whose occupation of the country was continuous from the days of the old river gravels? or had these long since died out, so that after Western Europe had for ages remained uninhabited, it was repopled in Neolithic times by the immigration of some new race of men? Was there, in fact, a "great gulf fixed" between the two occupations? or was there in Europe a gradual transition from the one stage of culture to the other?

It has been said that "what song the syrens sang, or what name Achilles assumed when he hid himself among women, though puzzling questions, are not beyond all conjecture;" and though the questions now proposed may come under the same category, and must await the discovery of many more essential facts before they receive definite and satisfactory answers, we may, I think, throw some light upon them if we venture to take a few steps upon the seductive if insecure paths of conjecture. So far as I know we have as yet no trustworthy evidence of any transition from the one age to the other, and the gulf between them remains practically unbridged. We can, indeed, hardly name the part of the world in which to seek for the cradle of Neolithic civilisation, though we know that traces of what appear to have been a stone-using people have been discovered in Egypt, and that what must be among the latest of the relics of their industry have been assigned to a date some 3,500 to 4,000 years before our era. The men of that time had attained to the highest degree of skill in working flint that has ever been reached. Their beautifully-made knives and spear-heads seem indicative of a culminating point reached after long ages of experience; but whence these artists in flint came or who they were is at present absolutely unknown, and their handiworks afford no clue to help us in tracing their origin.

Taking a wider survey, we may say that, generally speaking, not only the fauna but the surface configuration of the country were, in Western Europe at all events, much the same at the commencement of the Neolithic period as they are at the present day. We have, too, no geological indications to aid us in forming any chronological scale.

The occupation of some of the caves in the south of France seems to have been carried on after the erosion of the neighbouring river valleys had ceased, and so far as our knowledge goes these caves offer evidence of being the latest in time of those occupied by man during the Palæolithic period. It seems barely possible that, though in the north of Europe there are no distinct signs of such late occupation, yet that, in the south, man may have lived on, though in diminished numbers; and that in some of the caves—such, for instance, as those in the neighbourhood of Mentone—there may be traces of his existence during the transitional period that connects the Palæolithic and Neolithic Ages. If this were really the case, we might expect to find some traces of dissemination of Neolithic culture from a North Italian centre, but I much doubt whether any such traces actually exist.

If it had been in that part of the world that the transition took place, how are we to account for the abundance of polished stone hatchets found in Central India? Did Neolithic man return eastward by the same route as that by which in remote ages his Palæolithic predecessor had migrated westward? Would it not be in defiance of all probability to answer such a question in the affirmative? We have, it must be confessed, nothing of a substantial character to guide us in these speculations; but, pending the advent of evidence to the contrary, we may, I think, provisionally adopt the view that, owing to failure of food, climatal changes, or other causes, the occupation of Western Europe by Palæolithic man absolutely ceased, and that it was not until after an interval of long duration that Europe was repopled by a race of men immigrating from some other part of the globe where the human race had sur-

vived, and in course of ages had developed a higher stage of culture than that of Palæolithic man.

I have been carried away by the liberty allowed for conjecture into the regions of pure imagination, and must now return to the realms of fact, and one fact on which I desire for a short time to insist is that of the existence at the present day, in close juxtaposition with our own civilisation, of races of men who, at all events but a few generations ago, lived under much the same conditions as did our own Neolithic predecessors in Europe.

The manners and customs of these primitive tribes and peoples are changing day by day; their languages are becoming obsolete, their myths and traditions are dying out, their ancient processes of manufacture are falling into oblivion, and their numbers are rapidly diminishing, so that it seems inevitable that ere long many of these interesting populations will become absolutely extinct. The admirable Bureau of Ethnology instituted by our neighbours in the United States of America has done much towards preserving a knowledge of the various native races in this vast continent; and here in Canada the annual archaeological reports presented to the Minister of Education are rendering good service in the same cause.

Moreover, the committee of this Association appointed to investigate the physical characters, languages and industrial and social conditions of the North-Western tribes of the Dominion of Canada is about to present its twelfth and final report, which, in conjunction with those already presented, will do much towards preserving a knowledge of the habits and languages of those tribes. It is sad to think that Mr. Horatio Hale, whose comprehensive grasp of the bearings of ethnological questions, and whose unremitting labours have so materially conduced to the success of the committee, should be no longer among us. Although this report is said to be final, it is to be hoped that the committee may be able to indicate lines upon which future work in the direction of ethnological and archaeological research may be profitably carried on in this part of Her Majesty's dominions.

It is, however, lamentable to notice how little is being or has been officially done towards preserving a full record of the habits, beliefs, arts, myths, languages and physical characteristics of the countless other tribes and nations more or less uncivilised which are comprised within the limits of the British Empire. At the meeting of this Association held last year at Liverpool, it was resolved by the general committee "that it is of urgent importance to press upon the Government the necessity of establishing a Bureau of Ethnology for Greater Britain, which by collecting information with regard to the native races within and on the borders of the empire, will prove of immense value to science and to the Government itself." It has been suggested that such a bureau might with the greatest advantage and with the least outlay and permanent expense be connected either with the British Museum or with the Imperial Institute, and the project has already been submitted for the consideration of the trustees of the former establishment.

The existence of an almost unrivalled ethnological collection in the Museum, and the presence there of officers already well versed in ethnological research, seems to afford an argument in favour of the proposed bureau being connected with it. On the other hand, the Imperial Institute was founded with an especial view to its being a centre around which every interest connected with the dependencies of the Empire might gather for information and support. The establishment within the last twelve months of a scientific department within the Institute, with well-appointed laboratories and a highly trained staff, shows how ready are those concerned in its management to undertake any duties that may conduce to the welfare of the outlying parts of the British Empire—a fact of which I believe that Canada is fully aware. The Institute is therefore likely to develop, so far as its scientific department is concerned, into a bureau of advice in all matters scientific and technical, and certainly a Bureau of Ethnology such as that suggested would not be out of place within its walls.

Wherever such an institution is to be established the question of its existence must of necessity rest with Her Majesty's Government and Treasury, inasmuch as without funds, however moderate, the undertaking cannot be carried on. I trust that in considering the question it will always be borne in mind that in the relations between civilised and uncivilised nations and races it is of the first importance that the prejudices, and especially the religious or semi-religious and caste prejudices of the latter, should be thoroughly well known to the former. If but a single "little war" could be avoided in consequence of the knowledge acquired and stored up by the Bureau of Ethnology preventing such a misunderstanding as might culminate in warfare, the cost of such an institution would quickly be saved.

An Infirmary is to be erected by the Tendring Guardians and District Council, from the plans of Mr. F. Whitmore, Chelmsford, at a cost of 7,000*l.*

THE ROYAL ARCHÆOLOGICAL INSTITUTE.

ON the 2nd inst. the annual meeting of the Royal Archæological Institute began at Dorchester, under the presidency of Lieutenant-General A. H. L. F. Pitt-Rivers, Inspector of Prehistoric Monuments. In the course of his address (says the *Dorset County Chronicle*) he spoke on a subject which at the present moment occupies a considerable share of the attention of the archæological world.

The Palæolithic Period in Egypt.

The President said:—Mr. De Morgan, Director-General of the Antiquities of Egypt, in the preface of his great work on "Egyptian Origins" (1896), makes the complaint that the students of Egyptian history, engrossed by the enormous resources at their disposal of materials for the study of the metallic period, and the deep interest afforded by the interpretation of the papyri, and influenced also by the facility with which they are transported up and down the Nile in boats, instead of passing along the country landward, have paid less attention to the deposits on the sides of the Nile valley or to the discovery of the sites of palæolithic and neolithic man in that valley than has been done on the continent of Europe. This may have been partly true at the time when Mr. De Morgan's preface was written (1896), but since then the discoveries of Mr. Flinders Petrie and Mr. Seton-Karr have given abundant evidence of the existence of palæolithic man in the valley and the desert bordering it on the east side. Much earlier than this, however, in 1881, I claim to have been the first to discover flint flakes and cores *in situ* in the stratified gravels of the Nile valley at Koorneh, on the outskirts of Thebes, gravel in which, after having become indurated through the cementing together of the particles by calcareous infiltration, the Egyptians had cut their flat-topped tombs with square supporting pillars, that have continued perfect in the gravel-rock until the present day, thereby producing evidence of exactly the same character that had satisfied the fathers of prehistoric archæology in the valley of the Somme. Having experienced the drawbacks to careful study alluded to by Mr. De Morgan in travelling up the river as a Cook's tourist, I decided on arriving at Luxor to abandon the steamer and remain there whilst the boat went up to the cataracts and back, thereby giving me a clear fortnight for the deposits of gravel in the valley. I selected Gebel Assart, a plateau in the bottom of the valley to the north of Koorneh, consisting of a delta of hardened sand and gravel, which had been washed down by the Babel Molook, in which the tombs of kings are situated and spread over the valley below, and which, after depositing a delta in the valley between the sides of it and the river, had afterwards cut a channel through it by running water. In the sides of this channel, or waddi, the Egyptians had cut their tombs, tunnelling under the banks in the hard gravel, at that time converted into hard rock. After a careful examination of the sides of this waddi, extending over several days, I succeeded in finding unquestionable short flakes and cores, and one rough tool embedded in the matrix, which of course must have been deposited long previously to the cutting of the tombs, some of the flakes being actually chiselled out of the sides of the tombs.

This discovery was afterwards referred to at some length in a paper read before the Victoria Institute by Sir J. W. Dawson in 1884. Dr. Dawson, however, made the unaccountable mistake of saying that the flints found by me in this gravel were natural forms, and that the bulbs of percussion in them were caused by the knocking together of the fragments of stone by natural causes during the process of deposition. But he is mistaken in supposing that bulbs of percussion are formed to any extent in this way, as Professor Rupert Jones in his remarks upon the paper explained very forcibly at the time. If a single bulb of percussion could be so formed, which the examination of the constituents of the gravel show is very rarely the case, the production of all the recognised characters of a flint flake could not be obtained by this means. The production of a single bulb on the flat side of the flint, two or more facets at the backs with the impression of the bulbs of flakes previously struck off on them and the small flat surface at the top being the residuum of the flat surface of the core, on which the blow was given to flake it off, all formed by blows delivered nearly at the same spot and in the same direction, could not possibly be produced otherwise than by the hand of man. This is an axiom so thoroughly established as to be familiar to the merest tyro in prehistoric investigations. I had long experience at the time in the fracture of flint, and had been in constant communication and had worked with Sir John Evans, Canon Greenwell, Sir John Lubbock and the late Professor Rolleston, and it would have been quite impossible for me to have made a mistake upon the question of the natural or artificial form of a flint flake or core. In fact, I think that it would have been thought ridiculous by any of the well-known archæologists that I have named to suppose that I could have made such a blunder. Sir J. W. Dawson was of course a distinguished geologist, but his knowledge of prehistoric archæology was much more limited. There is nothing in his paper to show that he had ever seen the flints, of which

he spoke, and as they have always been in my possession I am aware that he could not have done so. Had he seen them I am certain that no one with the most rudimentary knowledge of the fracture of flint could have mistaken them for natural forms. It is true that my finds in these gravels did not include palæolithic implements of the tongue-shaped type that have been found in the desert and in the high plateau above the valley, from which deposits the flakes and cores were no doubt originally washed down into the delta below; but as the deposits in the bottom of the valley were as hard as rock nothing could be seen but the few specimens that were in evidence on the sides of the waddi and the sides of the tombs. Quarrying into the matrix itself would have been a very costly and laborious process, and though no doubt the usual palæolithic types would have been brought to light in abundance the flakes and cores were amply sufficient to prove them to be works of human art. A palæolithic implement of the recognised type affords no better evidence of the presence of man than a flake. The surface of the delta was covered with implements, and they had frequently been noticed on the surface by others, and after having discovered flakes and cores and one rude implement in the stratified deposits below there could be no doubt that the implements themselves would have been found in the same gravel if the rock had admitted of being dug into. Dr. Dawson himself admitted in his paper that there could be no doubt of the prehistoric period of the gravel, and all that was necessary was to show the presence of human handiwork in it to prove their immense priority to the Egyptian age.

It may be said perhaps that it sounds like ancient history to speak of discoveries made in 1881, when so much has been done since by subsequent explorers; and implements of true palæolithic type have been found both on the plateau land immediately above the Nile valley by Mr. Flinders Petrie and in the desert by Mr. Seton-Karr at some distance to the eastward of the Nile. This is quite true, but on the other hand the evidence of age afforded by the flints found by me in the deposits at the bottom of the valley so far as it goes is much better. The implements of palæolithic type found by Mr. Petrie and Mr. Karr, so far as I understand from their descriptions and their verbal communications to me, were found on the surface only. Flints found on the surface of the soil cannot be legitimately disconnected with flints of the surface period, except by form, and form alone is not conclusive in determining date. The same forms might have been used in different countries at different periods. I have little doubt from their number, and the absence generally of flints of a more advanced type amongst them, that they will eventually turn out to be of the true palæolithic age, but the evidence is as yet insufficient. And this makes it necessary for me to vindicate the character of my original finds, which have been aspersed by Sir J. W. Dawson. We have there, at any rate, evidence of the use of flint tools by man at a time long antecedent to the cutting of the Egyptian tombs, whereas in estimating the value of the surface finds above the valley we are met with the objection that there was nothing to have prevented a flint-worker from walking up the cliff with his flints and depositing them on the surface of the hills above at any period in the history of the valley. We must continue to rely on the *gisement*, as others have done before, and I have little doubt that it will be forthcoming hereafter, although the surface of the desert does not appear to favour the formation of sedimentary deposits. Mr. Seton-Karr informs me that the flints discovered by him were found lying bare on the surface of the top of a hill, from which the overlying earth had been denuded, probably by heavy rains. If so, the earth or sand so denuded must have been washed down together with some of the flints to a lower level, probably towards the bank of a stream or river which I understand passes through the ground on which the flints are distributed. It is possible that such flints may hereafter be found covered by deposits which had accumulated over them, and even that it may be possible to find with them the bones of extinct animals, which would at once show their place in the history of the district. Meanwhile a model of my finds at Gebel Assart, with the tombs and the stratification of the gravel, the original flakes and cores and a rough tool found in the deposits, has been placed in my museum at Farnham, Dorset, so that any visitor who has sufficient knowledge of the subject can estimate for himself the value of this part of the evidence relating to the antiquity of man. Mr. Seton-Karr has examined this model, and I have reason to think that when he returns to Egypt, which he intends to do in a few months, he will endeavour to obtain further evidence of the character that I have indicated.

Professor Clark proposed a hearty vote of thanks to General Pitt-Rivers for putting himself to the trouble and fatigue to come there and deliver that address. They had to thank him, not merely for his admirable paper, but also for his invaluable and continuous services to archæology, of which he might be considered as the head in England. A valuable step would have been taken towards the preservation of relics of antiquity if proprietors of land, acting upon the hint of General Pitt-

Rivers, absolutely prohibited any unscientific investigation and insisted upon scrupulous care in excavation and record.

Professor Boyd Dawkins, who seconded the vote of thanks, said he wished to acknowledge the great debt of gratitude they owed to General Pitt-Rivers. He was the first man to introduce method, accuracy and precision into those inquiries, and the result of his work, he was sorry to say, had not yet been fully grasped by the British public. He ventured to think that the work which he had carried out with pickaxe and shovel, and which was recorded in those magnificent volumes of his, had done more for the ancient history of the district than everything that had been written and done before, and he took it that the future historian of that part of the world would feel under a greater debt to his writings than to all the mere surface details which had been published before. Many years ago, more than he cared to think of, he obtained his schooling from General Pitt-Rivers in the method of working out earthworks, the use of the level, the contour and so forth; and his example, and not merely his results, would leave a profound mark on British archaeology. General Pitt-Rivers carried his method of precise investigation into Egypt, and was the very first man to trace home early flint implements in Egypt to their original parent rock. The rock-hewn tombs at Thebes yielded him full proof that before Egyptian civilisation there were rude people roaming through the valley of the Nile and using those flint implements. Until General Pitt-Rivers's researches came to the front there was no well-authenticated instance of a camp of the Bronze Age, and now they had four, of peculiar character and that curious square type. It was by no means impossible that the irregular square camp of Hod Hill might have been one of the Bronze Age fortresses, afterwards remodelled and occupied by the Romans. He could only give a faint and inadequate outline of the labours of General Pitt-Rivers, but it was a great pleasure to him, as a working archaeologist, to meet him on that platform.

General Pitt-Rivers, acknowledging the vote of thanks, said he was glad to see that in Dorchester so many people were beginning to take an interest in archaeological matters, as in these days little could be done without the support of the great masses of the population.

Round the Town.

The afternoon was devoted to a perambulation of the town under the guidance of Mr. Henry Moule. The party assembled at two o'clock at Maumbury Rings and surveyed with admiration the graceful contour of the amphitheatre. Mr. Moule observed the arena was not much smaller than that of the Colosseum. He could offer no explanation of the etymology of the word Maumbury.

Mr. Cunningham said that "maen" was the Anglo-Saxon for stone, and there used to be a large stone close by with a ring affixed to it, to which bulls were tethered. Bull-fighting was once very prevalent in the country. The rings were constructed by throwing up the chalk from all sides, the chalk being at this part about 300 or 400 feet deep.

Mr. Moule, being asked about the seating arrangements, said it was a moot point whether there were any seats at all. Some thought that the "swells" had their curule chairs brought out and placed on the ridges, and that the rest of the people stood. Stukeley and others said that the *caveæ* were on the south side, where the ground rose. That part of the amphitheatre was much damaged at the time of the Civil War, when the Parliamentary forces raised a platform and placed a battery there to command the Weymouth Road. In his early years the arena was under the plough.

Sir Henry Howorth stated that outside the circus at Lavinium a stone had been found bearing six words not devoid of humour. They were, "Circus plenus. Ingens Clamor. Janua—." The last word was obliterated. (A Voice: A standing announcement of "Full inside"—"Complet," as the French buses have it.)

Before the party left the amphitheatre Mr. Moule pointed to the line of foliage appearing over the roofs of houses and marking the site of the old walls of Dorchester. He declared that they were the first genuine boulevards in the world. He did not think any were planted in France till the end of the last century, whereas Stukeley had seen and commented upon these as early as 1723.

The party then returned to the town, and proceeded down the South Walks towards Fordington St. George Church. Mr. Moule pointed out the houses which had been built on the counterscarp of the foss, and stated that Mr. Alfred Pope, as he had anticipated, struck the foss in digging the foundations of his house. It was a remarkable section of the chalk, and there was good evidence of a glacis. Mr. Cunningham, while near All Saints Rectory, pointed out where the old wall stood. Next came a vallum 60 feet wide, then a foss 28 feet wide, a second vallum of 36 feet wide, a foss of 16 feet, and an outer vallum of 54 feet, making the process of a total width of 194 feet. Sweyn burnt the town in 1005, and threw down the

walls. Owing to frequent fires since then the lines of the old Roman streets had been lost. Durngate Street was once thought to be an original Roman road, but Mr. Thomas, a former borough surveyor, found a tessellated pavement right in the middle of the street, which clearly showed it was a mistake. Mr. Moule pointed out near Culliford House the place where the foundations of a gate, presumably Roman, were found.

On reaching Fordington St. George Church the antiquaries inspected with manifest interest the carved stone over the door representing St. George overcoming the Paynim. Mr. Moule, who expressed regret at the unavoidable absence of the vicar (the Rev. S. Boulter), made a few observations upon the church. It was, he said, very mangled, with an eighteenth-century chancel and a nineteenth-century aisle in the north. But, although mangled, it had several interesting features. By far the most interesting was the carved stone over the door, often called, but incorrectly, as he contended, a tympanum. The stone pulpit was of the Elizabethan age, its date being 1591. It was moved to its present position by his father, a former vicar, who discovered the rood-loft stairs, and shifted the pulpit in order to make the stairs serve as a means of ascending to it. Mr. Moule told how his boyish curiosity led to the holy-water stoup near the door being brought to light, and he narrated the popular story of how five of the peal of bells came from Bindon Abbey to Fordington, in accordance with the doggerel couplet:—

Wool streams and Coombe Keynes wells,
Fordington rogues stole Bindon bells.

The fifteenth-century tower was a fine specimen. Among Mr. Moule's own youthful reminiscences was the description of the member of the choir who, perched up in the old high gallery, sang the "Te Deum" as a solo in a broad Dorset voice, the congregation, who had remained seated, rising up at the close, facing the west, and singing the "Gloria Patri." In the churchyard attention was drawn to an old seventeenth-century tomb, bearing on the side the familiar epigrammatic inscription, "I was as thou art, and thou shalt be as I am."

St. Peter's Church was next visited. Mr. Moule described it as a graceful, pleasing fifteenth-century church. Close to that spot very probably stood the Roman temple, where the roads met, and there, too, when the empire became Christian, stood the first Christian basilica. He called attention to the various interesting monuments in the church—that to Lord Holles and the remarkable heraldic tomb of Sir John Williams, of Herringstone. The canopied niche inside the communion rails they might call a combined tomb and "Easter sepulchre" for the second host consecrated on Maundy Thursday. The effigies of the two knights in the windows did not belong to the church, but came from the Franciscan house at the bottom of Friary Lane. They were probably Chideocks of Chideock.

The party then walked up High West Street to see what Mr. Moule described as "the one still-standing fragment of the old wall of Durnovaria." They were next conducted by their guide down the Colliton Walks to view the remarkable scarp, where, as the low-lying ground was formerly a marsh or lake, no foss was possible or needed.

The party repaired next to the County Museum, where Mr. Moule doubtless felt himself even more than before on native ground. Alluding first and briefly to the natural history section, Mr. Moule said that their fossil collection was very fine. He had the authority of Mr. Smith Woodward, the expert on fossil reptiles and fish in the British Museum, for saying that theirs was beyond all comparison the best collection of those particular fossils to be seen outside the British Museum. Then as to their greensand fossils, Mr. Jukes Browne said that the geological world at large were quite ignorant that some fossils which were supposed to be found nowhere in England except in the greensand of Cambridge, were to be found in the middle of Dorset. Mr. Moule drew attention to the collections of Dorset birds and lepidoptera, and then proceeded to point out the most interesting antiquities, including a collection lent by Mr. Ralls, of Bridport.

The Antiquarian Section.

After the *table d'hôte* at the King's Arms, the members assembled at 8.30 in the room at the back of the hotel, where the antiquarian section was opened by Professor Boyd Dawkins with a thoughtful and erudite paper on "The Present Phase of Prehistoric Archaeology." In introducing the subject, he observed that the time was opportune and the place suitable for its consideration—the place, within the lines of a Roman fortress, surrounded by the relics of the ancient inhabitants of the ages of bronze and iron, the countless tumuli of the Downs and the fortified strongholds that kept watch and ward over Dorset. The great and as yet unbridged gulf between the Pleistocene and Prehistoric periods he instanced by asking what they knew of the Durotriges, in whose country they now were. Their place in British ethnology was a guess. Their habitations and fortresses, their manners and customs, were equally unknown to them; and that was the case in a land

called, after their name and abounding with remains which would lift the veil if explored by the scientific use of the pickaxe and the shovel. Dorset in its entrenched villages and fortresses was a veritable El Dorado from which, by the methods adopted by General Pitt-Rivers, untold archaeological wealth might be extracted. They had heard from the General that morning the story of the discovery of the fortresses of the Bronze Age, which had gone far to fill their blank in the annals of the South of England. Why not carry on the work and fill the greater blank of the prehistoric Iron Age? The scientific investigation of Hod or Hamildon hills, which might be done with comparative ease, would tell them more than anything they knew before on the matter, and would elucidate that portion of the past where the historic shaded into the prehistoric age. An interesting and often humorous speech commenting on Professor Boyd Dawkins's paper was made by Sir Henry Howorth in the course of proposing a vote of thanks. This was seconded by Professor Clark and carried with acclamation.

On the 3rd inst. Wareham and Corfe Castle were visited. The Rev. S. Blackett said that they in Wareham flattered themselves that they had in that building one of the most interesting antiquities—the relics of a Saxon church. Well, the shape of the east window viewed from the outside and the work in the quoins bore out what he said. The church consisted originally of nave and chancel, the aisle on the north having been an addition. It was said to be a twin church to St. Mary's, Bradford-on-Avon, and the proportions were exactly the same to a foot. There was an idea that that was in no sense a parish church, but a sort of missionary centre for St. Aldhelm, Bishop of Sherborne, who gathered a band of preaching monks around him and sent them about the country imitating him in his method of singing the Gospel. He had no doubt that St. Aldhelm himself often sang it there to the accompaniment of his harp. They had lately discovered the base of a group of four Purbeck marble pillars, of which the capitals remained. In 1673 about one-third of the town was burnt down, and some of the homeless inhabitants were given shelter in the church. It was even then not used for worship, and a brick fireplace was built in the corner for the people to cook their food. They were standing upon a perfect mass of human remains. He had no doubt that they used to bury there over and over again, and pushed aside the remains of one interment to make room for another. There were traces of very ancient paintings on the wall. Four distinct kinds had been traced there, and they could see the Royal Arms, the Ten Commandments, and the inscription to the Caruthers family. The east window was apparently never glazed, and outside could be seen the little holes into which the wickerwork was fitted to keep out the birds. The Society for the Preservation of Ancient Buildings considered that the western wall, close to which the cutting for the road had been made, should be underpinned to prevent it giving way. There was no intention to restore the building as a church, but he hoped to be able to preserve it, and once in every twelve months to hold a service there, so as to remind people that it was one of the ancient places of worship in the town, and was not to be kept up merely for show.

Mr. Micklethwaite said he quite accepted it as a Saxon church. It was hard to date Saxon work, but one of the criteria of late date was approximation to Norman detail. The chancel arch was not thoroughly Norman, but the jamb was. His impression was that the church belonged to the first half or middle of the eleventh century. He drew attention to the fragment of the hood of the characteristically tall Saxon door.

When the party left the church the whistle of Mr. Green, the honorary conductor, led them to a portion of the north rampart. The low-lying meadows were once all under water, and the road, which was still called the Causeway, marked the way into the town. Alfred the Great probably stood upon the very Causeway to parley with the Danes.

Mr. Blackett spoke of the frequent descents of the Danes upon Wareham, and said that Arne was their rendezvous when they harried the south of England. It was said that there were over sixteen churches in Wareham, and that the Danes were responsible for the destruction of eight of them. But it could scarcely be believed that so small a place as Wareham could have had as many as sixteen churches, and the truth probably was that eight churches were destroyed over and over again, and new names given to them when they were rebuilt, thus leading to the erroneous supposition that they were other churches. It was recorded in the Anglo-Saxon Chronicle that the Danes swore to Alfred that they would leave that part of the land. They sailed round Peverel Point and there were destroyed, partly by a storm and partly by Alfred's fleet. Near the Mowlem Institute at Swanage stood a pillar commemorating Alfred's victory, and bearing on the top a strange bit of irony, four cannon balls.

Sir Henry Howorth said it seemed to him that the walls were designed to keep out no other enemy than the sea. They were much like the ramps which surrounded many Dutch towns.

Mr. Moule objected to this theory that the walls went round three sides of the town, and that on the fourth side, where the

river flowed, and where the danger of the sea's incursion was greatest there was no wall.

Professor Boyd Dawkins also objected that the level on the ground inside the wall was so much higher than that outside that it was impossible for Wareham to have been submerged by the highest tide. He took the ramps to be for the purposes of fortification.

Mr. Blackett then led the antiquaries to the high north-west corner of the walls. He pointed out what was thought to be the old cockpit of amphitheatre, and the traces of the Roman road coming from Bere Regis. The still surviving names, North Port and West Port, indicated where two of the old gates used to stand, but the traces of the other two were entirely lost. That high and conspicuous part of the walls was called "The Bloody Bank," because the rebels taken after the Monmouth rebellion were executed there.

Mr. Cunningham said he had no doubt, after his investigations of years, that Wareham was a pastoral camp of the Durotriges, like Poundbury. To say that it was Roman was ridiculous. Stoborough, however, was the seat of a large Roman population, and there were potteries there.

Professor Boyd Dawkins said that these banks seemed to him from their irregularity not to be Roman. He should compare them with the irregular ramparts which surrounded ancient Silchester, in which they found the comparatively modern Silchester of the Roman time shrunk within the earthen rampart of the great centre of power in that part of the country before the Romans came. The ramparts, he was inclined to think, belonged to a time before the Romans came, and were intended to protect a population non-Roman and pre-Roman. From its geographical position no doubt that place must have been inhabited more or less from those days to the present time; but if Roman pottery was not found there in considerable quantity he should be inclined to think that it was not used much by the Romans. There were Roman roads there, but there were also traces of more ancient British trackways, one going due south and another running westward in an irregular line clearly marked on the 6-inch map. He therefore felt inclined to classify Wareham with such places as Poundbury, the ancient Silchester and the ancient town of St. Albans, the ramps of which were used for the Roman seat of Verulam.

Proceeding along the walls to the end, the party came to the church of St. Mary's. Mr. Blackett said that of the ancient church only the west and east end remained. The nave was destroyed and rebuilt about fifty years ago, when some magnificent Norman pillars 6 feet in diameter were, he believed, blown to pieces with gunpowder in order to make room for the present pillars. At the end of every aisle regularly was a chapel. Mr. Blackett told the well-known story of the murder and burial of King Edward the Martyr. The Twelve Apostles were carved in high relief around the lead bowl of the font. All the faces were battered to the obliteration of every feature, a piece of work for which Cromwell's soldiers got the credit. They were also said to have melted down the lead lid for bullets. The party spent some time in inspecting the recumbent effigies of Sir Edward and Sir William de Stoke, upon the armour of which, as indicating their age, Viscount Dillon made a few interesting remarks.

Mr. Blackett told how he discovered King Edward's Chapel, and led them into it. It was, he said, the church of the priory, which was close by, and the present church was built on to it for the use of the townspeople. He called attention to the groined roof and the two Roman altars. Thomas à Becket's Chapel, within the precincts of the communion rails, was afterwards seen.

Lord Dillon heartily thanked Mr. Blackett before the church was left for his painstaking and interesting description of Wareham.

Corfe Castle.

The Rev. O. L. Mansel, addressing the members under the shade of a tree, said he could tell them little which the late Mr. Thomas Bond, the great authority upon Corfe Castle, had not already told them in his exhaustive work, but he read the paper which he gave to the Dorset Field Club on their visit last year, with an apology to any of the company who might have been present on that occasion. This paper was published in the *Dorset County Chronicle* at the time. It described the history of Corfe from 690, when, as William of Malmesbury narrated, St. Aldhelm, Abbot of Shaftesbury, built a church there, down to the last and most exciting period of its existence. In 1635 the castle was purchased from Sir Christopher Hatton by Sir John Bankes, the ancestor of the present owner, whom he was sure that they would all wish to congratulate on his recent marriage. With few but vigorous strokes Mr. Mansel sketched the story of the siege heroically sustained by the little Royalist garrison under Lady Bankes against the host of Parliamentary besiegers, of how the castle was taken by treachery, and the decree for its demolition ruthlessly carried out. Mr. Mansel then led the company to the chief places of interest. He drew attention to how the ground rose by three natural slopes. It was on the highest ground that the first castle stood, pre-

sumably built by William the Conqueror, judging from its similarity in architecture to the Tower of London. The outer works were added in the reigns of Henry III. and Edward I. The company lingered some time on the site of the chapel of St. Aldhelm in the second court, and curiosity was expressed as to the reason why the fragment of wall built of herring-bone work had been left standing. It certainly was not for the purpose of defence, as the more modern curtain wall had been carried along outside it. Mr. Mansel asked whether it could have been, even at that early day, from a laudable sentiment of preserving old relics. If so, he only wished that that spirit had continued all down the ages since. Many members shared Mr. Mansel's opinion that the wall was the remains of an ancient Saxon building, and was left standing from motives of veneration; but Dr. Cox and others protested against the idea that because of its herring-bone work the wall must necessarily be pre-Norman. The party climbed to the keep and banqueting-hall, and then descended to the outer court, where tea was served. After this "refresher" the company drove back to Wareham and returned to Dorchester by train.

History and Historians.

Shortly before nine o'clock the historical section was opened at the King's Arms with a paper by Sir Henry Howorth, M.P., on "The Old and New Methods of Writing History." The paper was long, scholarly and frequently entertaining, brightened by gleams of that "sheet lightning" of wit and humour that ever seems to be playing in Sir Henry's mind. He expatiated first upon how often the functions of the poet and novelist were combined with that of the historian, and the results that proceeded from it. Whatever special branch of history was written of it should be in accordance with the rules of combined science and art as conceived by their highest votaries, and it must sweep away the crudities and amenities which crowded their book-shelves with ephemeral rubbish and marred their tempers in a search after truth where the germ of truth did not exist. History ought to be judged by the laws of evidence as observed in the courts of justice. Secondary evidence was not admissible where primary evidence was available. They must not call the copyist and compiler when they could get at the very sources, the *fontes*. He emphasised the importance of going back direct to the original sources of information, and of the stricter editing of those sources, in order to get the evidence in the purest form. To discriminate between different witnesses was the most trying part of the historian's duty. He deprecated giving a man a degree for history simply because he showed a retentive memory, and he declared that every aspirant for the honour should be required to write an original memoir. Sir Henry criticised somewhat trenchantly the work of certain well-known modern historians, and commended and recommended the methods of the German school. In conclusion, turning to archaeology, that important handmaid of history, he warmly praised and advocated the method of work adopted by General Pitt-Rivers. They all felt the enormity of the work done by old "restorers" of churches and destroyers of cathedrals, but they were apt to palliate and excuse the similar criminal who had mutilated their older, more fragile and less recorded monuments. He hoped that those having the custody of what remained would refuse to allow persons without the requisite training, knowledge and resources to tamper with those invaluable documents, the very title deeds of their earliest history, just as they would forbid a quack to treat their children or allow a person like himself to pull out their teeth.

On the motion of Professor Boyd Dawkins, seconded by Dr. Cox, a vote of thanks was accorded with acclamation to the lecturer.

(To be continued.)

The Nude in Greek Art.

SIR,—I thank you for inserting my first letter, and as this will be the last I shall write in answer to "Ronald Kelly," I shall feel greatly obliged if you can find space for it.

Since writing his first letter, "R. K." has not had much time to further study arts or morality; but you will notice that he is getting more polite, as, instead of styling us "brazen-faced apologies for girls and women," he speaks of the "new woman," and calls me "his fair opponent." How sweet of him!

He says, "I have written, believe me, conscientiously." I am sure he has, and I admire him for wishing to leave the world better than he found it. "R. K." seems to have "a bee in his bonnet," and it must be an absolutely nude one, for it worries him fearfully.

It is utter nonsense to say a nude figure, either male or female (especially the latter) is a vulgar sight. The pose of the figure may be. I have observed that men of strong animal passions when decorating (?) the walls of their own private sanctum, do not do so with reproductions of the pictures and statuary to which "R. K." objects, but with prints and photographs of ballet-girls and others *draped* in a style peculiar to themselves. Why is this? My answer is that the former, being a true and beautiful work of art, does not excite the animal passions, but the latter, being full of suggestion, does.

"R. K." makes use of the term "new woman." There are two kinds of the "new woman," the one whom a celebrated novelist styles "an understudy for a man"—she is a creature not truly admired by either sex. Then there is the "new woman" who has entered the different professions. Is she a curse? I venture to say not, for the following reasons:—It is now but a few years since the barriers which prevented her studying a profession were broken down. When she entered, what did she find?—men who through over-confidence had let "the cart run back." It did not take long for her to send many of the stronger sex to the wall, and of course these cried out; but the men possessed of grit did not fear her—they simply put their shoulders to the wheel and kept well ahead.

A clever man will always be superior to a clever woman, and in "life's race" a clever woman will experience the greatest pleasure in acting as pacemaker to a clever man, but he must be clever and able to convince others of his cleverness. "R. K." need not fear the mahl-stick; his first letter annoyed me, but his last has made me think of him "more in sorrow than in anger."

Now for that so dear to a woman, "the last word." If Mr. Kelly, when speaking of female art students, had not applied to them an expression which "thinking men" would not apply, even to members of the *demi-monde*, I should not have written these letters, because I am sure neither art nor morality will benefit thereby. A true man is by nature a gentleman. Is it therefore manly or gentlemanly to speak slightly of those you consider weaker than yourself?—I remain, yours faithfully,

A LADY ARTIST.

August 24, 1897.

GENERAL.

The Old Greek Church of St. Mary, Soho, is condemned by the London County Council as "a dangerous structure." It was the first Greek church in England, built in 1677 by the Archbishop of Samos, who recorded the fact in a Greek inscription still over the west door. It was subsequently occupied by Huguenots calling themselves "Les Grecs," and it is figured in Hogarth's picture *Noon*.

Lord Kelvin has been appointed honorary colonel of the corps of Electrical Engineer Volunteers now in course of formation.

The Late James Theodore Bent, the traveller and archaeologist, has left property valued at 21,497*l*.

The Bishop of Oxford has been re-elected president of the Bucks Archaeological and Architectural Society.

The Nelson Wesleyan Circuit's quarterly meeting has passed a resolution to erect two new chapels, each with a holding capacity for about 700 people, to cost 5,000*l*. each, one to be erected at Bradley Hall, the other in Barkerhouse Road. A Sunday-school is also to be erected at Barrowford, to cost about 2,000*l*.

Mr. Onslow Ford, R.A., has been commissioned to execute a statue of the Duke of Norfolk, in commemoration of his Grace's public services whilst Mayor of Sheffield.

M. Falguiere has completed the model of the statue of Cardinal Lavigerie which is intended to be erected in Bayonne. It is considered to be a successful likeness of the missionary bishop.

Mr. G. P. Hughes has ascertained by trial that most of the Californian and British Columbian species of coniferous trees thrive well on congenial soil and stations in Great Britain, and that as trees of ornament, shelter and commercial value they are well worth cultivating. Californian and British Columbian red wood now produces 1*s*. 11*d*. per cubic foot in the English market, the uses to which it is applied being the finer inside work of houses; yellow pine, 2*s*. 6*d*.; pitch pine, 1*s*. 6*d*. per cubic foot.

Professor Orsi announces the discovery in Sicily of several prehistoric quarries; some of them—as is shown by the numerous skeletons found on the spot—have been used as burial-places. Amongst the objects which came to light during the excavations are to be noted some stone knives, a great number of very primitive earthen vessels, showing for the most part the characteristics of the so-called first Sicilian period, a vase of the Dipylon style, and the fragments of a hydria with geometrical decorations.

The Architect.

THE WEEK.

CHICHESTER Cathedral impresses a visitor who sees it for the first time with a conviction that there is little care taken of the building. In such cases the Dean and Chapter are supposed to be indifferent; but the principal cause is the lack of money. An appeal by Archdeacon MOUNT in 1892 enabled a domus fund to be established, by means of which considerable repair has been effected. At that time the Chapter received from their surveyor, Mr. GORDON HILLS, a report upon the condition of the cathedral, most carefully drawn up, which embraced almost every matter of necessary repair which, in his opinion, should be submitted to the Chapter for their consideration. He estimated the cost of the several parts of the work at 11,555*l*. Large as is the sum, it is supposed to fall far short of what will be required to put the cathedral into a state of thorough repair. There are not sufficient funds available for so extensive a work. The executive committee propose, in the first place, to set on foot the rebuilding of the north-west tower, which has been pronounced to be necessary for the safety and preservation of the portion of the fabric originally supported by that tower before it fell. Mr. J. L. PEARSON, R.A., has been appointed as the architect to execute this part of the work. He has already furnished plans for it, and a responsible builder is prepared to carry them out for 6,250*l*. It is proposed to build so much of the tower as can be accomplished with the funds already subscribed, and to continue the work to its completion as subscriptions come in. The committee hope to be able to also undertake, as funds are supplied, the repair of the south transept, the renewing and repairing the dilapidated pavement of the nave and aisles, the re-erection of the nine pinnacles on the buttresses, which, in the opinion of the late surveyor, are required to "give weight and stability to those abutments," and the restoration of the ancient library over the chapel of St. John, but these works can only be accomplished at considerable cost. The sum of 3,606*l*. 10*s*. has been subscribed towards the general work of restoration. The committee ask all who have it in their power to assist them by donations and subscriptions, that they may be enabled to take in hand at once the rebuilding of the north-west tower and such other works of restoration as will rescue the cathedral from the injuries which it has sustained from the ravages of time and weather.

THE Sussex Archæological Society have revived the practice of visiting occasionally one or more of the ancient buildings of the county. Last week a commencement was made with Rotherfield Church, which is interesting not only on account of its history and style, but for the remains of mural paintings. Canon GOODWYN, who described the building, said there was probably some Norman work in the chancel, but the body of the church was Early English. The pillars on the north side were round, while those on the south side were octagonal, and there was no doubt that the present waggon-shaped roof had not always existed. At the door was an entrance which led to the priest's chamber, and under the floor there had been discovered a kind of stone altar, or rather part of a rude altar. The date on one of the panels of the canopy of the font was 1539, and the Canon believed it to be either the work of a French or Flemish artist. At that period the registers showed there was a considerable French colony in Rotherfield. There was another font, octagonal, like the pillars, which he had found in one of the fields in the neighbourhood, which belonged to one of the churchwardens in the year 1816. The pulpit had been placed in the church on last Palm Sunday. It was a very ancient pulpit, and had been brought from the Archbishop of York's chapel at Bishopthorpe, and erected upon a base of Crowborough stone. It bore a surprising resemblance to the pulpit in St. John's Church, Leeds. Mr. KEYSER considered the paintings possessed exceptional interest. Throughout the nave and in the lady chapel they could be found on every part of the walls. On the north splay of the window was a picture of

the Angel Gabriel, and on the south was one of the Blessed Virgin, and the other figures probably represented ADAM and EVE. In the splays of the blocked window to the right of the main entrance could be seen traces of a portrait of St. PAUL. All these pictures dated from the fourteenth century. On the south part of the east wall was a painting of the Incredulity of St. Thomas and other figures and ornaments, similar to those to be seen in Preston Church near Brighton. In some form or other the Doom, or Last Judgment, was represented in almost every church of that period in England. The Doom in Rotherfield was, with the exception of one in Clayton Church, about the most elaborate in England. The painting of the Doom to be found in the Patcham Church was the earliest example yet found. The opinion was generally expressed that some arrangement should be made between the Sussex and other societies for the preservation of such valuable remains of Mediæval wall-painting.

A NOVEL proposal was brought before the Liverpool City Council on Wednesday. Sir WILLIAM FORWOOD proposed that the right to raise rates on public buildings, and especially those devoted to education under the control of the Council, should be waived. The poor rate on the Art Gallery alone amounts to 321*l*. It was suggested that if that sum were set aside for the purchase, a good picture could be acquired for the permanent collection. The Liverpool Corporation do not advance money towards the purchase of works of art, and yet the collection is worth no less than 90,000*l*., while the buildings are valued at between 600,000*l*. and 700,000*l*. The Council's contributions towards the outlay amounted altogether to 10,000*l*. Some of the members were in favour of Sir WILLIAM FORWOOD'S proposal, others were opposed, but the debate on the subject was cut short, for the Town Clerk discovered that the proposal was contrary to law.

It is arranged that in connection with the National Home Reading Union some new courses will be introduced for 1897-98. One is a study of evolution through architectural styles; abundant references being given to the illustrations of successive types which are to be observed in Great Britain. There will be also special study of the art and archæology of Egypt. More entertaining for the majority of the members will probably be the study of the works of Sir WALTER SCOTT. They will be taken up not in the order in which they appeared, but in the chronological sequence of the periods in which their scenes are laid. A series of tableaux of English history from the twelfth to the eighteenth centuries will thus be presented to the reader, who at the same time will find in the work of the great novelist ample material for literary study. There is much else in the programme which is worth attention, and the Union deserves a large measure of support from young people and others.

THERE is no city in Europe which is more indebted to arboriculture than Paris. Take away the trees and the race of boulevardiers would be diminished, for those gentlemen believe there is no such delicate green to be found as can be seen from a chair in a café. What is no less remarkable, the trees appear to be as charming by night, and it is hard to say whether electric light or gas light is better adapted to display their beauty. But the trees have to be treated with as much attention as plants in a conservatory. This year they have fallen into "the sere, the yellow leaf" a little too soon, and "Tout-Paris" has raised an outcry against the Municipality and its officers. It was nature, however, that was to blame for an excess of precocity. The branches were covered with leaves as early as March. Early decay was therefore inevitable this year. Science has discovered no way to enable a tree to remain green in Paris for a longer term than five months. In spite of all the care bestowed on them it is equally impossible to keep off decay after a term of fifty years. That age is, however, a little in excess of what is allowed the average boulevardier, or rather what he allows to himself. The trees have acquired some of the qualities of the life of Parisians; and it is no wonder they are admired beyond those of the forest.

JACOB BURCKHARDT.

THE story about the German who evolved the idea of an elephant from his inner consciousness, and described the phantom at great length, is one of those which must always make the judicious grieve and pity the person who narrates it. Everybody who has studied works of art (and we suppose the same is true of natural history) must know, from his experience of the Germans he has met, that imagination exercises very little influence on them, for, at all sacrifices, they insist on seeing everything which is connected with their special subject. Neither engravings nor photographs are sufficient to satisfy the desire for knowing things. The originals must be familiar. Supposing, for example, a German considers there may have been some relation between architectural mouldings and those of Greek vases, he will not be satisfied until he has explored the principal collections in Europe, and has made a tour in Greece in order to obtain evidence. All his labour may never result in the production of a big folio with elaborate plates, but his conscience as a student will be at rest, for he has been able to confirm or to reject his own theory.

Among the inquirers who appear to require unceasing labour to obtain materials for a small book, JACOB BURCKHARDT, who died on August 8, deserves a prominent place. He could easily have compiled works on the history of art without departing from any of the colleges in which he taught; but if he had undertaken to write a pamphlet on the ornament of one of the South Sea islands he would consider he was incompetent for the task unless, after mastering the literature of the subject, he made a voyage to the island and lived among the inhabitants. We might even say that his love of facts and his indifference to everything that appeals to the emotions alone have had the effect of keeping his books unknown to a great many students outside Germany. While the names of WAAGEN, KUGLER, LÜBKE, RUMOHR and others are familiar in England and America, JACOB BURCKHARDT's excites little interest and his authority is rarely quoted. A few words about the late scholar will therefore not be out of place here.

He was born in 1818 at Basel, which might be described as the capital of Germanic Switzerland. Basel is a handsome town on the Rhine, and it possesses a fine cathedral, in which BURCKHARDT's father used to officiate as a minister, and other picturesque buildings. But for an incipient scholar it has another endowment in the associations with ERASMUS. JACOB BURCKHARDT exemplified in himself the influences of his birthplace. He was scholarly and owed allegiance to the lands in which the classics were produced; but he might have been, if he restricted his studies, an able architect or a painter. The modern life of Basel seems to be out of keeping with its Mediæval buildings. BURCKHARDT was too impressionable to be contented during his early years in the college classrooms. In common with many of his contemporaries he was not proof against the theories of SCHOPENHAUER, and his father's proposal to make a theologian of him did not mend matters. His only refuge from the weariness, flatness, staleness and unprofitableness of the world was in art, and to its history he devoted himself as a duty and as a relaxation. Accordingly, after going through the usual courses of training which Basel afforded, he turned to Berlin, where KUGLER was professor of the history of art in the Academy. It was also a period when great efforts were being made to create a school of painting which it was hoped would rival those of Italy in the time of the Renaissance.

BURCKHARDT applied the knowledge he had acquired in an essay on the cathedral of Basel, which was his first composition. In 1842 he wrote a little guide-book for tourists who wished to study Flemish art. The next year he selected as a subject CONRAD VON HOCHSTADEN—the archbishop who commenced the cathedral of Cologne. About that time he became acquainted with GOTTFRIED KINKEL, who a few years afterwards was an exile in London and was one of the pioneers in clearing obstacles and prejudices that impeded the progress of art among us. In his historical exercises the influence of LEOPOLD VON RANKE was apparent. The Berlin professor of history was described by MACAULAY as having “a mind fitted both for minute researches and for large speculations.” To some extent the words are applicable to RANKE's pupil, JACOB BURCKHARDT.

But fascinating as were investigations of the history of the minsters of Cologne and Basel, they could not subdue the voice which summoned BURCKHARDT to Italy. MIGNON's song, “Kennst du das Land” was always sounding in his ears, and he could hardly resist the impulse to see the columned halls, the statues and the paintings which abounded in that glorious region. Still more attractive to his scholarly mind was the vision of Rome. He succeeded in exploring the majority of places of Italy which contained a building, a picture, or a statue worth seeing, and yet his longing was not satisfied. The words with which he concludes “Der Cicerone” are almost pathetic, for, in fact, they are suggestive of that craving after the ideal which neither Classic art nor Renaissance art can assuage. Speaking of the Italian scenes of GASPAR POUSSIN and CLAUDE, and especially of the light which pervades them, “Whoever,” he says, “meets with the works of these masters outside Italy will find that they revive in him more effectually than modern works the home-sickness (Heimweh) for that unforgettable Rome which may slumber in the soul but can never die. That has been the writer's experience, and the best wish he can have for those who accept him as a guide is that they may enjoy such peace of the soul as was his in Rome, and which is revived whenever he looks on feeble imitations of the great masterpieces which once exercised their sway over him.”

“Der Cicerone,” which was the first product of BURCKHARDT's journey to Italy, which began in 1846, stands alone among guide-books. It suggests something that has been so repeatedly subjected to hydraulic pressure as to appear to have lost corporeal form. The reader feels that the author would have preferred to use formulæ in order to gain space, or to employ abbreviations for words. If with abbreviations and formulæ BURCKHARDT could have employed immense sheets on which to tabulate history and topography, so that much would be seen at a glance, he might then be happy. He was eager to present countless facts to the reader's attention, but he knew that travellers have no time for reading, and to accommodate them he has carried brevity to excess. In that way he is unique among Germans.

BURCKHARDT begins with the temple at Pæstum and ends with the imitators of CLAUDE, such as BOTH, MOLYN, ORIZZANTE and PANNINI. Between those extremes many are the revolutions in art which have to be chronicled. But the author's point of view is never changed. He has fixed principles which he applies as the works which exemplify Italian art during two thousand years are unfolded before him. He is therefore always impartial. Chronology instead of topography is the basis of his work. In architecture the order followed is Ancient, Early Christian, Romanesque, Gothic (Germanische), Early Renaissance, “Hochrenaissance”, Architecture from 1540 until 1580, Rococo (Barockstyle), Villas and Gardens. The architectural decoration of each period is considered separately. In sculpture the divisions are Antique, Mediæval, Fifteenth Century, Sixteenth Century, Rococo; and in painting Early Christian and Byzantine, Romanesque, Gothic, Fifteenth Century, Early Dutch and German, Glass-painting, Sixteenth Century, the Mannerists, Modern. It is not anticipated that guide-books are arranged on BURCKHARDT's system, and consequently “The Cicerone” is not as commonly seen in the hands of tourists as it merits. An effort is made by indices of places and artists to facilitate reference, but that is not considered enough. BURCKHARDT also wrote a “History of the Renaissance” and a treatise on “Renaissance Culture in Italy.”

A German of his type can hardly select his own method of living. As a distinguished student, BURCKHARDT was expected to teach in his turn. Accordingly in 1844 we find him holding office as supplementary professor of history in the University of Basel. In 1855 he was called to the Polytechnic Institute in Zürich, which at that time was considered to be the foremost establishment of its class in Europe. He was professor of the history of art. GOTTFRIED SEMPER was one of the professors, and both were almost sufficient to represent the Renaissance. BURCKHARDT was only allowed to remain three years, for his fellow-citizens felt they were not acting worthily in allowing another place to have the benefit of his ability. The

appointment of professor of history in the University of Basel was a tribute to his merit. Efforts were made to attract him to other universities, but he was faithful to Basel for the long period of thirty-five years. Even the offer to succeed RANKE in Berlin was rejected. He was so exact in attending to his professorial duties that his friends considered he did not do justice to the world and himself by the indifference to authorship which was displayed by the author of the "Age of Constantine." When new editions of his books were demanded he generally left the editing to one or other of his friends. In the case of "Der Cicerone" Dr. VAN ZAHN of Dresden was selected.

In 1893 BURCKHARDT, or rather his physicians, found there was risk if he continued in his onerous office as professor. He felt it was his duty to resign, although in doing so he was surrendering the delight of his life. The enforced leisure enabled him to take up some of his manuscripts, and it is understood that he completed two or three which related to his favourite subject, the Renaissance. A work by BURCKHARDT can never be superfluous, for wherever it was possible he had recourse to the original source of information, and always endeavoured to be consistent to his own principles in judging things.

ELECTRIC CABS.

OUR readers will have noticed in the daily press that electric cabs have been put on the streets lately, in such numbers as to make it evident that a really practical attempt is to be made to introduce motor carriages for other purposes than company promotion.

The outside appearance of these cabs is familiar to most of our readers, so it will be with the internal arrangements that we will chiefly deal. However, in passing, it may be well to mention that the company would be well advised to consider if the appearance of the under portion of the body can be improved, say by putting an outer casing over the battery box. This is slung under the body, is painted black, and is of such a shape that it is very conspicuous, situated as it is just under the light yellow body. However, this detail of appearance is of secondary importance at the present time. The essential point now is, Can a self-propelled vehicle be made to work noiselessly, reliably and cheaply? If the electric cab fulfils all these conditions (the first it certainly does), the rest will follow.

The cab resembles the single-seated brougham in appearance, but it is rather larger. The upholstery is really fine, being of leather. Spring cushions are used to minimise vibration, and the tyres are of rubber. Electric light is, of course, provided, both outside and inside the cab. The driver does not sit behind, but on the front of the vehicle. This is considered necessary with a motor carriage, owing to the fact that there is no horse to see where the cab is going.

The dash-board is rounded in front, and to some extent makes the cab look finished without the horse. At present, no doubt, the absence of the horse will be noticed, and for that reason the cab must appear incomplete—until one becomes used to it. When they have been running for a year or two, it will be possible to say whether they are really unsightly or not.

Each set of accumulator s consists of forty FAURE-KING cells having a capacity of 170 ampere hours at a discharge of 30 amperes, *i.e.* they will give 30 amperes for nearly six hours. The cab is said to take 24 amperes at full speed on the level if the road is good. The discharge of the cells is not supposed to exceed about 40 amperes under any conditions. The cells will thus give 80 volts and about 30 amperes for five hours—*i.e.* 2.4 kilowatts for five hours. The motor is of 3 horse-power, and this is ample for the work. The total weight of cab and passengers with motor and accumulators is said to be about 30 cwt., and the weight of accumulators alone about 14 cwt.

Any fears which might be entertained as to the commercial life of the accumulators is set at rest by the fact that the E.P.S. Company guarantee the maintenance of the cells for the sum of 10 per cent. of the first cost per annum. The Cab Company is thus relieved from anxiety and loss on the score of the accumulators. If the E.P.S. Company has made a good bargain, and if the guarantee holds good for perpetuity, there is no doubt that the FAURE-

KING cell has a great future. Ten years is rather a long life for an accumulator, and to guarantee this is a bold step under the conditions of running. It is true that the bad effect of vibration on the cells is considerably minimised by the method of suspension. The accumulator box is suspended to the cab framework by means of four springs, and there is no doubt that this is the best arrangement that could have been adopted. Another point in favour of the life of the accumulator is the excellent control arrangement for the motors. The motor is connected through gearing to the rear wheels of the cab, but there is no variable speed gear. The speed of the motor is altered, not the gearing ratio.

The motors, which have, we believe, been specially designed for these cabs, are of the JOHNSON-LUNDELL type, and are of American manufacture. The armature is wound with two distinct circuits, and there are two commutators, one for each circuit. The field windings consist of two similar series coils. This motor is then treated in the same way as the two motors are treated on a tramcar with a series parallel controller. To be more explicit, at full speed the two field windings are in parallel, and are in series with the armature, the two commutators of which are paralleled. At a slightly slower speed the field coils are placed in series, and the armature coils are still in parallel, the field and armature circuits being, of course, in series. At one-third speed the whole of the coils are in one series, *i.e.* the two armature coils are placed in series, and are in series with the two field coils. For starting a small resistance is thrown in series, being merely to ease the discharge of the cells until the cab is moving. The effect of placing the two armature windings in series is to halve the voltage on each coil, so that the natural speed is half of what it is when the windings are paralleled. The effect of putting the series windings in series is to make the full current traverse each, so doubling the magnetising force and considerably increasing the field over that which is obtained when they are paralleled and half the main current goes through each coil. The effect of increasing the field is to increase the torque or twisting force available, and it also again reduces the natural speed of the motor.

It will be seen that there are four speeds, in the slowest of which a resistance is used, but in all of the others the current is used very efficiently. The first speed is about 1 mile an hour, the second 3 miles an hour, which is about that of the well-known "crawl" of a cab, the third 7 and the fourth 9 or 10 miles an hour. At all these speeds, except the first, there is no waste, and the first is used only in starting. These connections are all automatically made by moving a lever forward; the amount the lever is moved determines the speed. If the lever is moved back from the "stop" position the first step short-circuits the motor through the starting resistance; the second completely short-circuits the motor; the third places all the coils in series and reverses the connections, making the cab run at slow speed backwards. The first step backwards makes the motor run as a dynamo and gradually brings the cab to rest; the second stops it immediately, if on the level; and the third, as before mentioned, either makes the cab run backwards or, if the gradient is very steep, tends to do so. A foot-brake of great power is used, which cuts off the current before applying the brake.

The steering is done by means of a worm-wheel and gearing, this being very simple and effective, and the worm-wheel has the great advantage of taking all strain from the handle, the wheels remaining in any position to which they are set without continuous holding of the handle.

The gearing has already been referred to. The motor pinion is of raw hide, or sometimes fibre, and this gears into the outside spur-wheel of a differential gear on a counter-shaft. This gear allows one-half of the shaft to move at a greater speed than the other while turning corners, &c. Each of the two back wheels is driven from this counter-shaft by means of the HANS-RENOULD laminating chain.

The small number of gear-wheels and absence of complication is said to make a very efficient gear, with which we fully agree.

There is no doubt that the whole arrangement of these cabs is very good and mechanical, and that they will be a success. Mr. BERSEY (the manager) is to be congratulated upon the result.

When we come to the arrangement of the works there is, perhaps, room for improvement in the future.

First, the mechanical arrangements. When a cab comes in it is run over a platform containing a trolley fitting the accumulator box. The platform is lifted hydraulically, and the battery is raised up and detached from the springs from which it hangs when on the cab. The cab is pushed away after the trolley and battery have been lowered. The trolley is then pushed on to another lift, when the battery is lifted to a higher gallery where it is pushed into its "stall" and is charged. It would be better to keep heavy accumulators on a ground-floor as much as possible, but perhaps circumstances, such as want of floor space, have made it necessary to have the gallery, but it is not a commendable feature.

The current for charging is obtained from the London Electric Supply Corporation's mains at $1\frac{1}{2}$ d. per unit. The pressure at which the electricity is supplied is 2,500 volts, alternating at 83 periods per second. This, of course, necessitated motor-transformers to convert the alternating high-tension current into a 100 volt continuous current. Two 75 kilowatt motor-transformers manufactured by the British Thomson-Houston Company are installed. These transformers give a 100 volt continuous current, which is led to the charging switchboard. From this switchboard a pair of leads go to each stall and are connected to the battery. One pole of the 100 volt circuit is connected to one lead from each stall. The other pole is connected to the other lead through an ammeter and adjustable resistance. There is a separate panel for each battery, these being provided for thirty-six sets at present. It is doubtful if this is the best arrangement that could be devised, but we await future results. Constant attention is necessary to keep the current at its correct figure, and the wisdom of putting in motor generators may be doubted by some. The electricity must cost the Cab Company at least 2d. per unit when delivered to the accumulators, owing to losses in the transformers, and there is at least a great probability that with a private plant of this size the cost would be less than this, as the work is of a continuous nature. With regard to the method of charging the accumulators, there is, we think, a better arrangement used with the Chicago accumulator trams. Three standard voltages are provided, and the discharged cells are first plugged on the lowest and subsequently on the other two; by this means there is no waste in resistances and very little attention is needed. However, the Electric Cab Company have opportunities to introduce improvements in future charging stations.

We were given an opportunity to test practically the running of the cab from the works at Lambeth to Westminster, and were agreeably surprised at the easy running and the perfect control exercised by the driver in and out amongst the traffic. We questioned him, and he said he had learned to drive the cab in a very short time—two or three days—and that he much preferred driving the motor to driving a horse. We feel sure that the company has a great future, and there is no doubt that they have produced a really practical self-propelled vehicle.

THE ART OF THE INDIANS OF BRITISH COLUMBIA.

AN investigation of the physical characters, languages and industrial and social conditions of the North-Western tribes of the Dominion of Canada is in progress by a committee of the British Association. At the meeting in Toronto Mr. Franz Boas produced a summary of the work in British Columbia. He gave the following information about the art of the natives:—

The decorative art of the Indians of the North Pacific coast differs from the arts of other primitive people in that the process of conventionalisation has not led to the development of geometric designs, but that the ornaments mostly represent animals. It is generally assumed that all the animal representations found on totem poles or on decorations of household utensils and of wearing apparel represent the totems of the various clans. While it is certainly true that in most cases the artists decorate the objects with the totem of the owner, there are a number of cases in which the reason for applying certain animal designs is founded on other considerations. This is very evident in the case of the fish-club, which is used in despatching halibut and other fish before they are hauled into the canoe. Almost all the clubs that I have seen represent the

sea-lion or the killer-whale—the two sea animals which are most feared by the Indians, and which kill those animals that are to be killed by means of the club. The idea of giving the club the design of the sea-lion or killer-whale is therefore rather to give it a form appropriate to its function, and perhaps, secondarily, to give it by means of its form great efficiency.

Another instance in which a close relation exists between the function of the object and its design is that of the grease dish. Small grease dishes have almost invariably the shape of the seal, or sometimes that of the sea-lion; that is, of those animals which furnish a large amount of blubber. Grease of sea animals is considered a sign of wealth. In many cases abundance of food is described by saying that the sea near the houses was covered with the grease of the seal, the sea-lion and whales. Thus the form of the seal seems to symbolise affluence.

Other grease dishes and food dishes have the form of canoes, and here, I believe, a similar idea has given rise to the form. The canoe symbolises that a canoe load of food is presented to the guests, and that this view is probably correct is indicated by the fact that in his speeches the host often refers to the canoe filled with food which he gives to his guests. The canoe form is often modified, and a whole series of types can be established forming the transition between canoe dishes and ordinary trays. Dishes of this sort always bear a conventionalised face at each short end, while the middle part is not decorated. This is analogous to the style of the decoration of the canoe. The design represents almost always the hawk. I am not certain what has given origin to the prevalence of this design. On the whole, the decoration of the canoe is totemistic. It may be that it is only the peculiar manner in which the beak of the hawk is represented which has given rise to the prevalence of this decoration. The upper jaw of the hawk is always shown so that its point reaches the lower jaw and turns back into the mouth. When painted or carved in front view, the beak is indicated by a narrow wedge-shaped strip in the middle of the face, the point of which touches the lower margin of the chin. The sharp bow and stern of a canoe with a profile of a face on each side, when represented on a level or slightly rounded surface, would assume the same shape. Therefore it may be that originally the middle line was not the beak of the hawk, but the foreshortened bow or stern of the canoe. This decoration is so uniform that the explanation given here seems to be very probable.

On halibut hooks we find very often decorations representing the squid. The reason for selecting this motive must be looked for in the fact that the squid is used for baiting the hooks.

I am not quite certain if the decoration of armour and weapons is totemistic or symbolic. Remarkably many helmets represent the sea-lion, many daggers the bear, eagle, wolf and raven; while I have not seen one that represents the killer-whale, although it is one of the ornaments that are most frequently shown on totemistic designs.

I presume this phenomenon may be accounted for by a consideration of the ease with which the conventionalised forms lend themselves to decorating certain parts of implements. It is difficult to imagine how the killer-whale could be represented on the handle of a dagger without impairing its usefulness. On the other hand, the long thin handles of lances made of the horn of the big-horn sheep generally terminate with the head of a raven or of a crane, the beak being the end of the handle. This form was evidently suggested by the slender tip of the horn, which is easily carved in this shape. The same seems to be true in the cases of lances or knives, the blades of which are represented as the long protruding tongues of animals; but it may be that in this case there is a complex action of a belief in the supernatural power of the tongue, and in the suggestions which the decorator received from the shape of the object he desired to decorate.

To sum up, it seems that there are a great number of cases of decoration which cannot be considered totemistic, but which are either symbolic or suggested by the shape of the object to be decorated. It seems likely that totemism was the most powerful incentive in developing the art of the natives of the North Pacific coast, but the desire to decorate in certain conventional forms once established, these forms were applied in cases in which there was no reason and no intention of using the totemistic mark. The thoughts of the artists were influenced by considerations foreign to the idea of totemism. This is one of the numerous ethnological phenomena which, although apparently simple, cannot be explained psychologically from a single cause, but are due to several factors.

The treatment of the animal design is very peculiar. We may distinguish two principles which govern the form of representation—first, the animal is characterised by a number of symbols; secondly, the artist does not endeavour to render a perspective view of the animal, but rather to show the whole animal.

The first of these principles is probably founded largely on the difficulty encountered in designing realistic representations

of various animals which would be clearly recognised as specific animals. For this reason the most characteristic peculiarities of each species become the symbols by which it is recognised. Thus the beaver is always symbolised by two large incisors and a scaly tail; the dog-fish by an elongated forehead, a mouth with depressed corners and five curved lines (the gills) on each cheek; the killer-whale by its tail, flippers and its large dorsal fin; the sculpin by two spines which rise over the forehead; the thunder-bird by a large beak, which is turned backward so that it touches the chin. Probably all these symbols were originally applied to characterise a portion of a quadruped, bird or fish, but in course of time they came to be considered as sufficient to call to mind the form of the whole animal. We find therefore that gradually the symbols were to a great extent substituted for representations of the whole animal. A dorsal fin worn on the blanket of a dancer, or painted on his face, indicates that the person so decorated personates the killer-whale. A strongly-curved beak painted on a gambling-stick symbolises that the stick is meant to represent the thunder-bird. A protruding tongue painted on the chin symbolises the bear.

The second principle seems to be quite opposed to the first one. When the artist decorates any object with the representation of an animal, he distorts and dissects the animal in such a way as to show the whole body on the decorative field; but a closer examination of this tendency proves that it originates mainly in the necessity felt by the artist of introducing all the symbols, which are distributed over the whole body of the animal, in the decoration. To give a few instances, bracelets are decorated in such a way that the animal is split along its back, and then represented in such a manner as to make it appear as though the arm were pushed through the opening. On tattooings the animals are shown as split through along their backs or along their chests, and then flattened out, so that a symmetrical design results. Carvings on totem poles must be interpreted in the same way, the animal being represented as bisected along the rear side of the totem pole, and extended so that the two margins of the cut appear on the borders of the carved portion of the pole. The distortion and section of animals is nowhere carried further than in representations on boxes, on slate dishes, and on Chilcat blankets; but in all these decorations we recognise the endeavour to bring such forms of the animal into view as are essential for an understanding of the design; that is to say, all those parts of the animal are represented which serve as its symbols.

So far as I am aware, the process of conventionalising has not led to the formation of geometrical designs, which are exceedingly rare on decorated objects from the North Pacific coast. They are found only in certain kinds of basket-work and in mattings.

SAM BOUGH.

IT is understood that a book on the late Sam Bough, the Northern landscapist, is in preparation by Mr. Pennington. The author's competency to deal with so perplexing a subject is suggested by an article in *Good Words*. The following extracts from it will reveal Mr. Pennington's sympathy with the wayward artist, while he is not oblivious of the shortcomings of his character. That Bough raised or lowered himself to the level of his companions for the moment, and in consequence was sometimes unfairly judged, is plain from what Mr. Pennington says:—

As in the case of Burns, Bough has been and is yet misunderstood, because the measure applied to him is, as a rule, too small. Many who flatter themselves upon knowing him intimately never in reality saw more of him than the clothes he wore. We do not speak of Bough's duality, but of his multiplicity, his well-nigh infinite variety. He could be rude in both manner and speech, and his acquaintances were habituated to sarcasm and *brusquerie*. He had, in consequence, many friends, but a multitude of enemies, who have passed into currency many stories of his wild conduct. These have led others who only knew by hearsay one, and that the worst, side of his character, to invent many cruel and repulsive fictions about him and his ways. These may safely be discounted to the extent of about 90 per cent. Mr. William McTaggart, R.S.A., tells of a sketching excursion which he had with Bough. It lasted three days, during which they were hardly ever separate, either night or day. On starting Bough opened what proved a sustained flow of informing, high and often eloquent discourse. The natural gentleman had left his clown's mask at home, and the broad humourist was supplanted by the suggestive and brilliant conversationalist. They had done little more than reach Edinburgh when they were met by two or three of his boon companions, and in an instant Bough was transformed. He knew what was expected of him, and he stepped down into the gutter and ministered unto them. It may be said that he should have made a better choice of associates, and he may not have been blameless. It is, nevertheless, unfortunate that men can always be found willing to drag down a meteor wherewith to light their parlours. That may be said of Bough and of

them which the farmer of Covington Mains said of Burns and his apologists:—"One-half of his good and all his bad divided amang a score o' them would make them a' better men." It is worth remembering that men do not talk who have no listeners.

Some of the peculiarities of Bough's early life are thus described:—Sam was a Bohemian by heredity, a born humourist and an artist by divine endowment. After leaving the service of the Gilpin family, James Bough turned clogger—maker of clogs—and shoemaker. He was a man of quiet temperament, fond of having the poets read to him while he worked. Sam's Bohemianism came to him through his mother. Describing him lately to the present writer, one of his school companions said he was a "wild, mischievous and dilapidated youngster." He rarely went out through the door if the window was conveniently open. He cared less about dress and appearances than even the laxity of his mother could tolerate. He was much addicted to giving chase to young girls and frightening them. His education, however, grew apace and when he was old enough he entered the office of Mr. Nanson, town clerk, with a view to qualifying for the legal profession. Two years satisfied him that the law was not his vocation. He was drawing when he ought to have been copying and vastly preferred the open book of nature to the pages of Blackstone and Coke. Imparting his love of art to Mr. Nanson, that worthy gentleman declared him to be "the biggest fool he had ever set eyes on." Whether Sam took his liberty or got it from Mr. Nanson is not clear. He was still a youth when he went touring through the country in gipsy fashion, with donkey cart and tent. His companion, sutler, groom, chancellor of the exchequer and man Friday in general was John McDougall, a native of Oban, who had been a soldier in the 91st Argyshire Regiment. John was a Peninsular veteran, who finished his fighting at Waterloo. Sam sketched and painted, and, when the treasury ran low, it was John's high function to sell the sketches and paintings to the best advantage. Long afterwards, when a member of the Royal Scottish Academy and settled in Edinburgh, Bough often looked back longingly to the free life of his youth. His happiest days were passed, he said, when he rambled about Cumberland, sleeping either in barns and out-houses or under canvas with McDougall.

Of Bough's life in Edinburgh it is said:—The key to Bough's later life and mature character is now in our hands. Take this athletic and rambling painter, who loved nature with a devotion too deep to plumb, away from the tent pitched among the fells and dales of Cumberland, and from the only less free life of the theatre, and transplant him to the cold, chaste reserve and rigid formality of Edinburgh, and what was he likely to find but ice atop and ice-water under? He was too full of life to care for the lifeless fabric called society. His heart was too great, and its beat too strong, for him to obey loveless social law. Hence he openly ridiculed the stately ceremony which society had stamped with the sacred seal of its approval. He laughed at convention, set at defiance the laws devised for the regulation of social intercourse, and swept aside every restraint upon individual freedom. It requires an effort to picture Bough sitting "mim-mou'd" and trying to be proper and mannerly, in kid gloves and starch, wearing the orthodox broadcloth and stiffened breastplate of social righteousness. When, therefore, he wished relaxation, he unbraced himself in a section of society where men at least met each other face to face, without either mask or disguise.

The following examples of Bough's good-nature are given:—No friend in need ever appealed to Bough in vain. None of his kindred, whether remote or near, suffered want while he had anything to share. The ties of blood he held sacred. Once he resumed a discarded suit of clothes, parcelled up his new suit, and carried it under his arm to his studio to give it to a wandering mason-sculptor from Carlisle. Again, when going home from a late party he was once accosted by a theatrical acquaintance in poverty. Bough dropped behind, and the two men disappeared in an entry. When Bough rejoined his friends he was minus his overcoat. In evening dress he faced the bitter wind of the winter morning for sweet charity's sake. Why multiply instances? "Brave, generous and good, kind and gentle"—such, in truth, was Bough.

In conclusion, Mr. Pennington says:—Speaking in more general terms, Bough bore himself in art as he did in society. He rose above the conventions of his predecessors, and painted not only what he saw but what he thought and felt. In rendering atmospheric effects, particularly those prevailing in broken weather, when the sunshine is dashed on sea and land in flakes, when the wind is high and mists are gloomy and dank, he had for many years no rival. And, further, in suggesting what no artist could paint, he filled the great blank in the earlier landscape art of Scotland. Looking for affinities, we assort him with Constable, David Cox, Muller, Copley Fielding and Cattermole, and yet we never lose sight of Bough. He was so versatile, that while he painted strange scenery in a manner at once magnificent and broad, he could turn his brush to the most delightful treatment in water-colours of the portrait of a

Skye terrier. His style changed from canvas to canvas, from theme to theme. It was not small and stereotyped, but large and elastic. He came to Scotland with the turn of the tide from mannerism to the higher impressionism—the expression of individuality, the painted outcome of the artist's self—and when he passed the source was dried up of an influence which had always made for the exaltation of art.

ELSTOW CHURCH.*

WE are visiting to-day a place of no common interest. It is not indeed situated within the county of Hertford, to which some would desire to confine the researches of this Society, but while not far from our borders, it forms a subject respecting which no members of a society like our own can afford to be ignorant. The historical interest of the place is twofold; the antiquarian will remember that it is one of the most valuable relics of a Royal Foundation for Ladies assuming the rule of St. Benedict, and will note every fragment of a church and its surroundings bearing on the history of so interesting an establishment, while some will view Elstow with another though later interest, as the home of the pious mechanic who has left to the Christian world, in the "Pilgrim's Progress," an allegory which no less an authority than the late Lord Macaulay has declared to be a masterpiece. We saw in passing the cottage in which John Bunyan lived, much altered indeed, but containing the beam, I am told, from which chips have been dispersed throughout the world, as sacred relics in many lands. We have seen the green (now through the late drought all too yellow) on which as a youth the yet unconverted man sported, and where he believed his conversion to have taken place. We are near the tower where he rang the bells till a serious dread of them seems to have possessed him. For we are told that he loved in his youth of all things best dancing and ringing. The first he discontinued after marriage, and if church ringers then were what unhappily some of us can remember such to have been before the late reform in our belfries began, it is easy to understand why a religiously-minded man objected to their companionship. We too have lately crossed the river formerly spanned by an ancient bridge on which stood a chapel, as we see to this day lower down the course of the Ouse at St. Ives, turned at Bedford into a house of detention, and familiarly believed, though the circumstance has since been doubted, as the place where the first inspiration of the "Pilgrim's Progress" seized Bunyan's mind when in brief captivity there, and which he describes thus:—"As I walked through the wilderness of this world I lighted on a certain place where was a cave and laid me down to sleep, and as I slept I dreamed a dream." Before leaving the thoughts of one whose name is inseparably connected with this place and neighbourhood, I may remind you that we possess in our own county and in my own parish a picture believed on the best authority to be an original likeness of John Bunyan. It was discovered by the late Rev. John Olive in a very bad condition in a cottage in the village of Codicote. He purchased it and had it carefully restored. This portrait has been seen on the occasion of one of the excursions by our Society in Wheatthampstead House, while it was also carefully studied I understand by those who had charge of the erection of the monument which we hope to see at Bedford this afternoon. I may mention again that under the guidance of the late Dr. Griffith, some few years ago our Society visited the remains of a cottage at Coleman Green in the parish of Sandridge, where it is generally believed Bunyan lodged and preached, for the labours of this good man, though far extended, took him generally to quiet places, though we may well hope that his efforts for good were treated with a more liberal toleration by those who must needs differ from his teaching than the efforts of some others in nonconforming history. For Bunyan appears to have had friends and even admirers in the Church, and to have been finally released from restraint by the aid of Thomas Barlow, afterwards Bishop of Lincoln.

I have touched on the life of this marvellous man, because it is impossible to visit this place without thinking of it, but beyond ringing in the detached campanile of this church, and occasionally worshipping within its walls, his history is unconnected with that more ancient history in which an archaeological and architectural society must find its chief interest. Let me then for a few minutes touch on this. The name Elstow, spelt Elnestow in the Domesday survey, is a corruption of Helenstow, and the place is so named in consequence of the dedication of the conventual church to St. Helen, the mother of the Emperor Constantine, her name being associated in the dedication with the Holy Trinity and that of St. Mary. The Countess Judith, niece of William the Conqueror and widow of Waltheof, Earl of Northumberland, Northampton and Hunt-

ingdon, here founded a conventual establishment for Benedictine nuns. The days following that terrible Conquest were days of great Church activity; the spoilers had seized great wealth, and it has been regarded as a fact by high authority that many of their buildings were works of expiation. Those were troublous times; many fair lands were wasted by fire and sword, and refugees were frequently to be found alone in the houses of the religious. It might have been that there was some sanctuary here before, but the authentic history of the place begins with the foundation of Judith, who became its first abbess. We cannot view the interior of this stately fragment without being certain that we are within no ordinary church. There is a height and dignity about it which marks it as a remnant of a great abbey church, though one of but two stages, for we must observe that the triforium stage is absent. There can be little doubt, too, that the easternmost bays are part of the structure of Judith, and that in accordance with the decoration of that date they were once richly coloured. It is stated by those who have studied the structure and had some means of excavation that the constructive nave extended one bay further eastward than we now see, and they believe that a central tower, transepts, apsidal choir and lady chapel completed the church in that direction. What we see now here of Norman work is suggestive of the usual Benedictine arrangement; for the ritual choir, as at St. Albans, would extend two bays into the constructive nave, and one more westerly bay would be provided for a procession path. It often happened that this was as much as one generation of abbey builders could accomplish, and if so much was done, the church was complete as far as its choral requirements went, and was structurally sufficiently supported to stand. This is about what has been accomplished at the new Truro Cathedral in our own times, though there the choir follows the more usual cathedral arrangement, and its fittings do not extend beyond the eastern piers of the central tower, which they usually did in the Benedictine churches. If we are correct in our views, here we shall find the western limb of the Norman church before us, while the rich Early English extension, dating from, say, early in the reign of Edward I., would form a short nave. I put its conjectural date, for we have no documentary evidence, I fear, during the reign of Edward I., for we find curious examples before us of the buckle ornament, which a great authority, the late Mr. Hartshorne, has regarded as a certain indication of the time of that king. These arches are a beautiful study, and their massive piers are well adapted to carry on the lines of their Norman and more eastern predecessors. There is an elegance and peculiarity in the foliage arrangement here which is suggestive of ladies device; it is seen in the junction of mouldings, on their springing from the caps, as at the western portal. At this west front were apparently porches something like, though much smaller, than those at St. Albans, for the arcading which appears to have enriched them is to be seen upon the adjoining buttress. One most beautiful and remarkable feature is that which is believed to have been the chapter-house, a vaulted building with central Purbeck shaft constructed very shortly after the Early English extension of the church. The vaulting is remarkable and the shaft is peculiarly beautiful. Here probably the ladies of the monastery sat with the abbess in council. Some writers speak of the usual cloister adjoining, but I confess I see no traces of it, or find head room for its construction as the south windows of the nave are now. The cloister was the scriptorium of monks; but did nuns need such places of literary labour? I speak for inquiry and correction. From the chapter-house a covered way would doubtless lead to the domestic buildings of the nunnery, which must have occupied the site of the fine house which the receiver of the abbey property at the dissolution built out of its dishonoured stones. One relic of extraordinary interest and value of a religious house of unusual fame is the brass of one of its latest abbesses, the Abbess Elizabeth Hervey. We see her in the robes of her office and holding her pastoral staff; but one other example remains in brass, and one only of a Benedictine abbess in stone. For a full description I must refer you to a most interesting paper by the late Mr. Bloxam, published in the Bedford Architectural Society's Transactions, included in the reports and papers of the Associated Societies for the year 1863, and I also find in these reports a very valuable paper on the church of Elstow by Mr. George Hurst. We have these in our St. Albans library, and I had them at hand in writing my paper. Mr. Hurst's paper was apparently read here in 1855, and its illustrations show the state of the church before its restoration in 1880, for we miss now a screen which appeared formerly to mark the limits of the ancient choir; the old pulpit, too, now consigned to a corner, there appears *in situ*. The restoration of 1880, under the care of Mr. T. J. Jackson, architect, of Bedford, appears to have been very carefully done, and the present condition of the church bears witness to much reverent love. Would that more of it had existed at the time when it was wholly robbed of its many possessions and not even a pittance left for the ministrations of religion within it. One remaining and unusual feature I must

* A paper read by the Rev. Canon Davys to the members of the St. Albans Architectural and Archaeological Society in Elstow Church, and published in the *Herts Advertiser*.

notice in the massive detached bell tower. It belongs chiefly to so late a period of architecture that it has been supposed to have been erected after the dissolution of the abbey with its old materials. It has been thought, however, to rest on the foundations of an older campanile of large proportions, which would account for the width of its base and the contractions at its various stages. It must be, however, considered as a remarkable tower, for except at Chichester we have but few detached campaniles remaining out of a good many once provided at our cathedrals and large abbey churches.

THE STATUE OF RAPHAEL IN URBINO.

A CORRESPONDENT of the *Daily News*, writing from Urbino, says:—

On Sunday morning, August 22, at half-past ten, a beautiful statue of Raphael was unveiled here in the presence of the Minister of Public Instruction and a large concourse of people. The ceremony of unveiling was most imposing. Besides the Minister Gianturco there were present the Syndic of Urbino, the communal councillors, the representatives of scholastic institutes and of other public bodies. The monument is the work of the sculptor Belli, of Turin. The figure of Raphael, which stands upon a massive granite pedestal, is represented in his working dress, and is a graceful and lifelike portrait of "the divine painter." He stands in the attitude of contemplating from afar the effect of one of his works. In his left hand he holds a palette, a paint-brush being in his right. The pedestal is in the cinque-cento style, the ornamentation somewhat resembling the decoration of the Ducal Palace at Venice. At the front and at the back of the pedestal are beautiful groups taken from the works of Raphael; the little angels from the pictures of the Madonna di Foligno, of the Baldacchino and of the San Sisto. One group symbolises painting, the other sculpture. Upon the dado of the pedestal are bas-reliefs, one of which represents Raphael at the Pontifical Court painting the portrait of Leo X. with two cardinals. The other one represents him intent upon directing the decoration of the Loggie of the Vatican. On either side of the pedestal is seated a figure; to the right is a woman of Greek outline in the act of divesting herself of a mantle which enfolds her, and who symbolises the Renaissance of Art; to the left is a Genius, of Michelangesque pose, who holds on high a crown of laurel. Festoons of laurel on the dado bind together the coats-of-arms of the cities of Urbino, Perugia, Florence, Siena and Rome. The medallions at the base reproduce, from authentic documents, the portraits of Bramante, Timoteo Viti, of Perugino, Giovanni da Udine, Pierino del Vaga, Francesco Perroni, Giulio Romano and Marcantonio Raimondi. The statue of Raphael, together with those of the Renaissance and of the Genius of Art, as also the medallions, are all in bronze. The groups of angels, the ornamentations and bas-reliefs are executed in Carrara marble. In unveiling the statue, the Minister for Public Instruction made an excellent speech, which was frequently interrupted by applause. He spoke of Raphael's love for his country, and of the happiness of his life in having near him his idol Michel Angelo, as Mozart had Beethoven. The orator spoke of Raphael as poet as well as painter, and, recalling to mind his great dream of restoring the classic Roman monuments, he said that under the auspices of King Humbert that dream would be realised. Signor Gianturco afterwards inspected the monument, accompanied by the sculptor Belli, whom he cordially congratulated upon his beautiful work.

A splendid bronze wreath has been sent to Urbino by the Municipality and Academy of Fine Arts of Perugia, to be laid upon the monument of Raphael. The International Exhibition in honour of Raphael was inaugurated at Urbino on Sunday. In the evening the city was illuminated, and gala performances were given in the principal theatres. The Minister of Public Instruction attended the opening of the exhibition.

CAMBRIAN ARCHÆOLOGICAL ASSOCIATION.

THE members and visitors of this Association on the 18th ult. repaired to St. David's and its district. The country visited abounds with objects of surpassing interest to the archæologist, and, it being impossible to examine all, attention was confined to objects more recently discovered. The first stopping-place was Brawdy Church. At St. David's the Rev. Chancellor Davey read a paper on "The Architectural Sequence of the Cathedral Building." After luncheon the Ven. Dean of St. David's took a party through the cathedral, and explained points of interest in detail. Later in the day the Dean took a party round the chapel and Holy Well at St. Non's, the traditional birthplace of St. David. Mr. H. W. Williams conducted a party to St. David's Head, where he explained the alignments, the unique features in the hitherto undescribed outer wall which Mr. Henry Owen and he

discovered last year, and the village within the well-known "Clawdd y Milwr." He showed that this wonderfully-preserved stone-walled camp was built by the people of the Neolithic Stone Age, dressed stone having been found within the walls under circumstances which settled this question once for all. In the walls, which are now for the most part lines of fallen stones, Mr. Williams showed portions of the original cyclopean masonry, and he pointed out the curious little stone-built cells which, for want of a better name, have been called sentry-boxes. One of these was marvellously preserved, considering that it must have stood the buffets of time for many thousands of years. Upon the party returning to St. David's the members and visitors became the guests of Dean Howell. The return journey was begun at 6 P.M., Haverfordwest being reached at 9.30 P.M.

The next morning (Thursday) was devoted to an inspection of the objects of interest at Haverfordwest. The castle claimed attention first, and St. Martin's, St. Mary's and St. Thomas's Churches and the Priory were each in turn visited. At 12.30 a start was made for St. Leonard's Rath. This was described by Mrs. Allen and Mr. H. W. Williams. It is a British rath, with earthen vallum and fosse in very perfect condition, including an inner court. It is one of the largest and most perfect raths in the county and is unique, inasmuch as it has a water supply, and consequently must have been a very strong position. Wiston Castle and Church were next visited. This castle is evidently built upon an earlier foundation and was the scene of some of the bloodiest battles which were fought between the Welsh and English. It was described by Mr. E. Allen. Going thence towards Llayhaden the Association passed through Colby Moor, which was the scene of a battle during the Civil Wars. Llawhaden Castle, which is situated on the banks of the eastern Cleddau, presented a number of most interesting features. It was built by Bishop Beck about the thirteenth century. Llawhaden Church was also visited. A stop was made on the way back at Picton Castle, the residence of Sir Charles Philipps, who invited the members to partake of tea. Various objects of interest in and around the castle were examined. Among the more interesting objects were a beautiful groined ceiling supporting one of the bastions, and a dungeon under the keep. Near the dungeon is a small room having a window. It is stated that during the Civil War, when this castle was besieged, a nurse holding one of the children of the then occupier at the window was observed by one of the enemy, who ran up, snatched the child from the arms of the nurse, made it prisoner, and took it to the camp of the besiegers. In order to ransom the life of the child, the holders of the castle were obliged to capitulate. The armoury of the castle contains a number of the firearms used by the Cromwellian troops. The portion of the building now used as a hall is magnificent in its structure. Above the main entrance is a room now used as a chapel, which forms one of the most interesting features of this Mediæval fortress. The fortress is itself in a very perfect state of preservation, and its interior has been little changed from the days when it was used as a defence. After votes of thanks to Sir Charles and Lady Philipps, the company drove back to Haverfordwest.

A general meeting was held at night under the presidency of Archdeacon Thomas, when it was decided to hold the annual meeting next year at Ludlow, Shropshire.

UNIVERSITY COLLEGE, LONDON.

THE following prizes and certificates have been awarded in the courses of architectural lectures and architectural and constructional drawing and quantity surveying at University College, as the result of the work and examination of the session 1896-97:—

Architecture.—Professor T. Roger Smith, F.R.I.B.A. *Fine Art*.—Donaldson Medal—M. H. West, of Maidenhead. Prize—G. G. Lean, of Isleworth. Third Class—E. Martineau, of Hastings.

Construction.—Donaldson Medal—C. F. Dawson, of Barking. Prize—F. J. Freeman, of Blackheath. Second Class—H. S. R. Boyajian, of Kharput; G. G. Lean, of Isleworth. Third Class—E. Martineau, of Hastings; W. P. D. Stebbing, of London.

Classes Maintained by the Carpenters' Company—Architectural Drawing.—1st Prize—J. Porter, of London. 2nd Prize—P. H. Pape, of London. Certificate—E. C. Desch, of London.

Construction Drawing.—1st Prize—A. E. Stump, of London. 2nd Prize—W. Smalley, of London. Second Class—A. S. Kilby, of London; A. Pethybridge, of London; A. Thwaite, of London.

Quantity Surveying (Elementary Class).—Prize—W. B. Payne, of London. (*Advanced Class*)—Prize—H. C. Simmons, of London. Second Class—T. A. Burr, of London; W. Smalley, of London. Third Class—H. B. Ward, of London.

NOTES AND COMMENTS.

PHOTOGRAPHY alone can render justice to the myriad details which are to be found in some buildings. With no less truth we may say that only by its help are the phenomena of geology to be represented. It has, however, one shortcoming, as it cannot render the colours of rocks. The committee of the British Association for obtaining photographs of geological interest have already succeeded in obtaining 1,751 examples. Among the more notable donations of the year are a large series of views in Wealden strata, some in the Nottingham district, a very instructive series from North Staffordshire, a set from the Sgurr of Eigg, a series of Yorkshire caves, sets from County Dublin, Yorkshire, and the Isle of Man, several from North Devon and the Isle of Wight, and a most useful group from the North of Ireland was also given. There still remain many areas of great geological interest in England, Scotland and Ireland which, as yet, are not represented in the collection. Photographs of areas of large and typical physical features, such as the Pennine and Pendle Ranges, the South Wales coalfield and its borders, the district of the Arans, Arenigs and Cader Idris, the Harlech Mountains, the Yorkshire Dales, the Cotteswolds and South Downs, the Malverns and the Silurian ground of the Welsh border, the Yorkshire Moors, Lincolnshire, the area of the Northampton Oolites, the Oxford district, Seaton and Blackdown, Central Wales and Anglesey; in Scotland, the North-west and Central Highlands, the Outer Hebrides, Mull, the Sidlaws and Ochil Hills and the Southern Uplands; in Ireland, the Carlingford and Slieve Gallion areas, Kerry, Cork, the Limerick Basin, Waterford and Wicklow are much desired by the committee. The collection now contains photographs of the more sensational geological phenomena. What is required is the steady surveying of ordinary, and especially temporary, features and phenomena. Picked points on retreating and advancing shore lines should be photographed at regular intervals; sections in variable deposits should be taken as the excavation of them proceeds; and out-of-the-way districts should also be registered, even if they only yield ordinary phenomena. Important as it is that fossils should be accurately and faithfully figured, it is equally essential that phenomena in the field should be figured in a way that is not only accurate, but includes, without accentuation, the interpretation of the investigator, while it registers facts which may have escaped his observation. The collection is deposited in the Library of the Museum of Practical Geology, Jermyn Street. The hon. secretary of the committee is Professor W. W. WATTS, Mason College, Birmingham.

It is proposed to hold a "Pan-American" exhibition in 1899. The site proposed has novelty in its favour. It is Cayuga Island, containing about 175 acres in the Niagara River and a few miles above the Falls. From its proximity to Niagara it is in communication with many parts of the United States, which send about half a million of people yearly to visit the cataracts. The neighbourhood of so vast an amount of power has suggested to the promoters that electricity should predominate in the exhibition, including the restaurants, where the products of electrical cooking will be obtainable in a variety of forms.

THE public library at Strasburg was famous for examples of early printing, as became a city where a press was set up in 1436. It also contained several illuminated works by Mediaeval and Byzantine artists. Altogether there were about 100,000 volumes in the building. The destruction of the library in 1870 has not added to the credit of the Germans. But there was, it appears, not the least intention to make war on books and librarians. According to M. VICTOR ELBEL, who was engaged in defending Strasburg, the original cause of the burning of the library and its treasures was a draughtsman's error. On a plan of the city which had been prepared for siege purposes in Berlin, the group of buildings in the Rue de la Mésange, consisting of the New Temple, Gymnase and Library, were described by the word Rathhaus, a building which is in the Brandgasse. It is not to be expected that war should be free from errors, and although the error in naming has had lamentable consequences, it is not one which is unknown on ordinary maps.

Hardly a year passes but instances of draughtsmen's oversights are brought under the consideration of the Parliamentary examiners under standing orders.

ALTHOUGH tendering is a familiar process, there appears to be no recognised rule about the liberty to make alterations in tenders prior to acceptance. Two recent cases suggest the difference of opinion on the subject. On Monday in Stourbridge the tenders for the decoration of the town hall were considered. The highest tender amounted to 686*l.* 14*s.* 6*d.*, the lowest was 244*l.* 4*s.* There is perhaps nothing extraordinary in the variations. The committee entrusted with the work decided on the acceptance of the lowest tender. Subsequently they were informed that the amount should have been 284*l.* 4*s.*, if it were not for a clerk's blunder. When altered the tender remained about 75*l.* below one which stood next in amount. The contractor said he was prepared, if the Council insisted, to carry out the work at the unaltered price. Another competitor wrote to say if revision were allowed in one case it would be unfair unless the privilege were extended to all. The committee considered they were bound to accept the revised tender, as it was the lowest; and the Council adopted that view. In Colchester a similar case occurred last week. But one of the aldermen was a brother to a member of the firm that had sent in the erroneous tender, and he insisted on the principle that alterations should not be allowed in tenders, and the work therefore was entrusted to another firm, although at a higher amount. It seems to us that the Stourbridge Council were more equitable. The fairest way of getting work done is to pay according to schedule prices; and accordingly there is more or less speculation and uncertainty in tendering for a lump sum. No employer should wish to have a contractor work at a loss, or to bind one to an amount that is unquestionably wrong. It is, however, well to remember that an erroneous tender can be made binding on a contractor, unless there is an understanding that the signing of some contract or other deed is an indispensable condition.

ONE effect of the catastrophe in the Rue Jean Goujon is to make the authorities unusually anxious about the condition of the theatres in Paris. The Prefect of Police has announced that he must have at least a fortnight's notice concerning the time when theatres can be examined, in order to ascertain whether all the alterations ordered by the Commission on Theatres are carried out. Until his certificate is obtained the reopening of a theatre will have to be postponed. The responsibility for delay and loss is therefore cast upon the managers.

SOME sort of impetus is needed to make the occasional exhibitions in the Manchester Art Gallery successful. Mr. J. E. PHYTHIAN told the Manchester Council on Wednesday that while the permanent collection had been steadily growing, they had been endeavouring to hold the annual exhibitions, until now it was impossible to have a satisfactory exhibition in the autumn without doing injustice to the pictures in the permanent collection. Last spring they offered the public a Tudor exhibition, which they did not care for, and, so far as the attendance was concerned, it was a failure. Then the attendance at the autumn exhibition had been steadily going down, until instead of 50,000 or 60,000 people visiting it, the attendance had dropped to something like 20,000, or even less. The committee had had before them a proposal to so modify the autumn exhibitions that they would lose altogether their present character and importance. The matter lay very largely in the hands of the public. In view of the exhibition about to be held, the committee would be guided to some extent in the decision they came to by the interest shown by the public in that exhibition. The Art Gallery, which is used for permanent and occasional exhibitions, is not worthy of a city like Manchester. But while the Corporation are liberal in purchasing pictures, they will not expend money on building. At present the works of art appear of inferior value on account of their setting, and as long as there is not a fine and capacious gallery visitors will not take the trouble to glance at the pictures, although they are costly.

BRIXTON FREE LIBRARY.

BOTTLING AND MINERAL WATER DEPARTMENT, ETC., FOR THE OLDHAM BREWERY COMPANY, LIMITED.

THESE premises have a frontage to Coldhurst Street of 129 feet, and are 58 feet deep. They are divided absolutely in two departments, one being for beer-bottling and the other for manufacture of mineral waters. Each department is complete in itself, having separate wash-houses, loading docks, &c.

In the basement it is divided into two large and lofty cellars, the boiler-house being in centre and under washhouse. The cellar on left hand is used as bottling cellar, the other as storage for bottled beer. The top floor is devoted to syrup-rooms and rooms for storage of empty bottles, &c.

Small office and hoist are provided, the latter having WORRALL'S patent hoist gates, which open and shut automatically, worked by the mechanism of the hoist itself. The hoist was provided and fixed by Messrs. BARKER, of Oldham, who also fixed travelling crane in bottling cellar used for lifting barrels of beer on and off the stillages. There is a chimney 30 yards high.

Cellar floor is formed of concrete, finished with granite face. Centre floor is fireproof, having steel girders and joists filled in with concrete, and finished with patent rock asphalt, rendering same waterproof. Top floor consists of 3-inch tongued and grooved planking, fixed on strong joists and iron beams.

The whole of the ceilings are boarded with pitch-pine boards and varnished. Roofs to washhouses have continuous lantern lights with strong glass louvres, and are glazed on top with patent glazing. Glazed bricks from JOSEPH BROOKS & SONS have been largely used in bottling-rooms and wash-houses.

All staircases throughout are entirely of cast-iron, made by J. HALL & SONS. The areas in front are finished with HAYWARD'S patent prismatic lights. All rain-water pipes are of strong lead, and are fixed inside recesses in walls, being arranged to receive same, and covered with movable boards, the bottoms of each stack being provided with patent trap and inspection chamber for cleaning out.

The whole of inside walls, also front outside, are faced with Messrs. S. & J. SMETHURST'S bricks. The contractors for the building were Messrs. J. & D. BLUNN, of Oldham, the architect being Mr. CHARLES T. TAYLOR, A.R.I.B.A., 10 Clegg Street, Oldham.

THE ROYAL ARCHÆOLOGICAL INSTITUTE.

(Concluded from last week.)

PROMPTLY at nine o'clock on the 4th August a train of brakes left the King's Arms bearing the members of the Institute to the monastic shades of Sherborne. The weather was again fine and hot. Short halts were made at Cerne and Middlemarsh.

Sherborne Castle.

About noon the vehicles pulled up outside the Old Castle, to which Mr. Wingfield Digby, M.P., had granted admission. Here the party were received by Mr. W. B. Wildman, one of the masters of Sherborne School, and an enthusiastic student of the antiquities of the town, on which he is doubtless the best authority. Mr. Wildman, who had kindly undertaken to conduct the party over the various buildings of archæological interest, expressed Mr. Digby's regret at being called away from Sherborne that day. The company entered the delicious shade thrown by the trees in the turf-carpeted castle court, and Mr. Wildman described the buildings and told their history. He thought that the Saxon bishops of Sherborne had their dwellings on the platform which existed there before the castle. The Norman castle was built by Bishop Roger, of Sarum, between 1107 and 1139. The tower was of close-jointed Norman masonry, and as Bishop Roger was the first man who built in that style, they were at the very spot where it was first used. It was not, strictly speaking, a fighting castle, but rather a fortified palace, and the chief house of the bishops of Sherborne. When the bishopric was transferred to Salisbury the castle continued to be the great house of the bishops of Sarum till Queen Elizabeth

took it away and gave it to Sir Walter Raleigh. About 400l. a year was still paid to the Bishop of Salisbury out of the manor of Sherborne, and that was the only relic of his lordship of the place. When Sir Walter Raleigh was attainted for high treason the whole estate passed to the king. The first Earl of Bristol, the first of the Digbys, was ambassador in Spain, and King James, being unable to pay him his salary, let him have the estate. The castle was taken and destroyed by Cromwell. After inspecting the principal parts of the old ruin the company were conducted to the dairyhouse adjoining the new castle, and shown the fine Roman tessellated pavement. It was unearthed at Lenthay, about two miles west of Sherborne, during the laying of the railway, and taken up and relaid in its present position, in a room where old china and other curiosities are displayed. The middle of the pavement represents two figures, one standing and blowing a double pipe and the other sitting and playing a six-stringed lute. The bordering is elaborately ornamental. The party made the circuit of the modern castle, Mr. Digby's residence, and then walked to the Digby Hotel and had luncheon.

The Abbey Church.

After luncheon the party reassembled at the abbey church, which was inspected outside and inside under the guidance of Mr. Wildman. He observed that it looked like a fifteenth-century building with a few Norman details; but really there had been three churches there—first, the church of St. Aldhelm, which must have been founded at the end of the seventh or beginning of the eighth century; secondly, the Norman building of the twelfth century; and thirdly, the present Perpendicular church built in the fifteenth century, and practically a restoration of the Norman church. Of the Saxon church only one small portion was left. It ended westward where the west wall now stood. It had a porch at the west end and two slender unbuttressed towers. In the fourteenth century a parish church was built on at the west end of the abbey church. The north aisle still remained with the six bays. In 1540 the parishioners bought the abbey church and began to sell the parish church for building stone. The whole line of buildings must have presented an imposing appearance, comprising, going from west to east, the parish church with a western tower, the abbey church nave, tower and choir, and then the lady chapel, an Early English building. Within the abbey church Mr. Wildman expressed great admiration of the vaulting in the choir. He had seen the chief Perpendicular buildings of England, and had observed nothing more beautiful. The vaulting of the north transept was even finer. Abbot Bradford he believed to have commenced the work.

The School Buildings and Alms-house.

The buildings of Sherborne School close by were next visited. Mr. Wildman led the party to the middle of the cloister court of the abbey, and showed the spot where once stood the conduit, now removed to the Parade. He pointed out the dormitory coming from the north transept of the abbey church, the chapter-house, the refectory on the north side of the cloister court, the guesting room on the west, and the building now used as the school chapel, which was the abbot's own hall, and had been considerably enlarged. At the lady chapel Mr. Wildman pointed to the site where King Alfred must have been educated, and observed that no place had anything like the same claim to Alfred's boyhood as Sherborne had. Mr. Wildman then conducted the antiquaries through the dining hall, on the site of the original abbey schoolroom, the twelfth-century Norman undercroft, which was the oldest part of the school, and then the library and schoolroom. He observed that the history of Sherborne School came down from 705, with a break of eleven years from 1539 to 1550. The last place visited was St. John's Hospital. Mr. Wildman stated that it was founded in 1437, the very year the church was built, by four pious individuals of the neighbourhood, with the commendation and support of the Bishop of Sarum. It originally accommodated twelve old men and six old women, but the inmates were now eighteen men and nine women, elected by the master and brethren. The hospital possessed a good deal of valuable house property in the neighbourhood, and had an income from endowment of close on 800l. a year. The plan of the building was originally the same as that of the great alms-house at Lübeck. It was early fifteenth-century work, but very good. On leaving the building Lord Dillon warmly thanked Mr. Wildman on behalf of the Institute for having in so able and interesting a manner shown and described the antiquities of his town, about which he displayed so much enthusiasm.

Mr. Wildman, acknowledging the noble President's remarks and the acclamation of the company, declared that it had been a great pleasure to him, for there was no place of which he was prouder than the town in which he lived.

Judge Baylis moved and Professor Clark seconded a vote of thanks to Mr. Digby for admitting the Institute to his grounds.

At 4.30 the carriages left Sherborne, homeward bound.

Soirée at the Museum.

In the evening a brilliant and successful social gathering took place at the County Museum.

The annual business meeting of the Institute was held on the 5th ult. The six members of the Council retiring by rotation were re-elected, and all the officers continue in office. At two o'clock brakes started for the two fine earthworks which the neighbourhood of Dorchester boasts of—Poundbury and Maiden Castle. A fresh breeze was blowing, and after the sultriness of the previous days proved very pleasant, and made walking quite exhilarating on the grassy heights.

Poundbury.

The company having seated themselves in a sheltered part of the western foss, Mr. Green, the hon. director, stated that Professor Boyd Dawkins, who was to have spoken on both earthworks, had been unavoidably called away. Professor Boyd Dawkins thought the camp pre-Roman—in effect the pre-Roman town of Dorchester. In shape it had something of pre-Roman irregularity and something of Roman squareness, the latter suggesting that the Romans occupied it after the prehistoric men had left it. He pointed out the track of the early British road, and stated that hut circles had been found in the bottom below, from which the inhabitants doubtless moved into the camp in time of danger. Dr. Boyd Dawkins had called his attention to the curious fact that Dorchester, in Oxfordshire, had exactly the same kind of surroundings as Dorchester, Dorset—the river camp, distant camp, and trackways in all directions.

Mr. Moule, who was asked to speak, said that when the railway was made it took all the antiquarian influence of the day—Mr. Warne, Mr. Barnes and others—to save the camp from being cut right through, and to get a tunnel substituted for a cutting. But when the cutting leading to the tunnel on the east side of the camp was made, it was proved to be, not the simple earthwork that it now looked, but a remarkably elaborate one, for outside the foss and vallum were found three more fossæ. Mr. Robert Hunt had told him that twenty-three years ago, when his cousin, Mr. Arthur Legg, was tenant of Poundbury Farm, they came to break up a piece of Fordington down, about a mile or a mile and a half west. When the furze was being cleared away they found from 200 to 300 hollows in the ground, about 6 or 8 feet in diameter, and a large number of them in two parallel rows. There were flints lying in the bottom of them, and they were undoubtedly hut circles. An enclosure half a mile west was a cattle pound, showing that the occupants were a cattle keeping tribe.

Mr. Cunningham informed the company that they were now within the old town of Dunium, mentioned by Ptolemy in the second century. He had dug from end to end of the western foss, and found plenty of Durotrigian material—flints, and very old ones, and British pottery. It was refreshing that the Danish origin of the camp was now given up for good. When the Romans came and conquered they threw down the southern and eastern valla, as he had found Roman material covered up in them. The whole history of the place had been written by him and was ready for publication. In expressing the thanks of the Institute to the three speakers, Lord Dillon observed that an interesting feature of all very early earthworks, as General Pitt-Rivers was one of the first men to point out, was the great knowledge they had of the proper system of fortifying the ground. It was left for General Pitt-Rivers first to vindicate the engineering art of their early ancestors. If they reconstituted the original position, making allowance for the sinking of the valla and the silting up of the fossæ, they would find that there was, in military parlance, no "dead ground," that is, no spot close by where an opposing force could rally in numbers preparatory to making a final rush. Mr. A. Pope said they should impress upon Mr. Cunningham the importance of not delaying the publication of his history of Poundbury. Dorchester people had looked forward to it with great interest, being aware that Mr. Cunningham knew more about the place than any living person. He hoped that the Institute would use their influence to persuade Mr. Cunningham to give them the benefit of his work in print. Mr. Moule said he had seen Mr. Cunningham's manuscript, and the drawings and sections illustrating it, and he thought that if the Institute put on two or three more turns of the screw it would be done.

Maiden Castle.

Leaving the breezy height of Poundbury the party drove to Maiden Castle, gained the inner camp by the old western entrance, and walked right round the rampart, stopping here and there for a little description and comment. Mr. Green again expressed regret at the absence of Professor Boyd Dawkins, whose observations they had all been expecting with interest. He declared it to be the finest fortification of its kind in England, and drew attention to its size, its deep trenches and strong traverses. At the middle of the south rampart Mr. Cunningham pointed out what he said was originally the principal entrance and the road leading to it. This road he

had traced as far as Jordan Hill, near Weymouth, the basis of the Roman operations against the Celtic inhabitants. General Lefroy was there in 1865 and said that the earthwork was made by men who had large resources in immense variety at their beck and call. Only disciplined forces could have constructed the wonderful demi-lunes and traverses. An entrance eastward took one to the amphitheatre. Mr. Moule called attention to the ramp dividing the camp into two unequal portions. He said that the late Mr. Warne had an idea that the eastern half was an old Celtic encampment, and that when the Romans penetrated so far west several Celtic tribes forgot their tribal differences and united against the common foe. They said, "We cannot hope to keep our little camps, like Chalbury and Poundbury, but we will combine to defend this and make it larger and stronger." Before they could finish their work Vespasian was upon them, and the use and occupation of the place by the Celts was at an end. He did not discountenance the idea that the depression near the middle of the south ramp marked the site of the well. At Mr. Moule's request Mr. Robert Hunt, who had joined the party at Maiden Castle, told in his own words the story of the finding of the hut circles near Poundbury. The spot was shown where Mr. Cunningham had found the remains of a Roman villa. It having been brought to the knowledge of some of the leading archaeologists present that Mr. Cunningham believed in a Roman origin to the camp, he was sounded on the subject and led to make an unequivocal declaration. He maintained that the whole was Roman work *de novo*. The Celts would never have thought of making anything there with an ascent of only one in an hundred, for if those massive ramparts were put back in their places they would come to that gradient. General Pitt-Rivers, who came there with him, expressed the same opinion—that it was the work of disciplined forces. He asked the General what he thought of the place, and he answered, "I will not tell you, Cunningham, until I have dug thoroughly into it." The late Mr. Warne, when he was dining with him once, said he would give anything if only he could convince him (Mr. Cunningham) that Maiden Castle was a British work. He answered, "Nothing shall convince me." The Romans were there without doubt under the leadership of Vespasian, who in 67 was called away to undertake the siege of Jerusalem, and they knew what great works he constructed there. Sir Talbot Baker stoutly opposed Mr. Cunningham's conclusion that the earthwork was Roman, and asked what in the world could be the use of such castrametation to soldiers who had catapultæ and other projectile engines as the Romans had. Dr. Cox declared that 99 out of 100 of all who had the least experience of earthworks would take that to be undoubtedly a pre-Roman work. A mere tyro would come to that conclusion. It was, however, impossible to decide as to the origin of the work by merely digging here and there, and, as Sir Henry Howorth and Professor Boyd Dawkins had said, without systematic investigation. At the business meeting of the Institute that morning the opinion was expressed that there was no place in England which so demanded or would so thoroughly repay systematic investigation as Maiden Castle, which is the most gigantic and magnificent earthwork that the country possessed. The finding of Roman remains, or even of a small Roman villa, only proved that the Romans occupied the camp, not that they made it. Mr. Cunningham was inconsistent, because at Wareham, where Professor Boyd Dawkins found an intelligent man who had a collection of Roman things discovered there, he declared that the Romans never had a finger in making the works. "Disciplined forces," too, need not necessarily be Roman, but existed long before the time of the Romans. Sir Talbot Baker: Is any camp of this construction Roman? Is not the Roman method of castrametation as straight as he can make it, with north, south, east and west gates? Here we have an extraordinary convulsion of mounds and ditches. Lord Dillon, in thanking Messrs. Green, Cunningham, Moule and others for their remarks, said he hoped that they would not agree too well. Too much agreement resulted in idleness, and he trusted that they would continue to pick holes in one another's theories until the truth had been found.

The party then returned to Dorchester, but this was not the end of the animated debate. It was resumed the following day, when the company were sitting upon the grassy hill at Abbotsbury, in front of St. Catherine's Chapel, and commanding a glorious view of the Chesil Beach and the West Bay. Professor Boyd Dawkins, whose opinion is justly valued so highly by the Institute, and whose absence was so felt the day before, was now present. He expressed regret at being unable to be with them at Maiden Castle the day before, owing to having to attend a Local Government Board inquiry in London, and to state that Maiden Castle was one of a large series of fortresses which were occupied in the prehistoric Iron Age, long before the name of Roman was known on that side of the Channel. Professor Boyd Dawkins had risen to speak on the Chesil Beach, but at the urgent request of several members he added a few remarks about Maiden Castle. He considered that it was pre-Roman because in camps of that class things prior to

the Roman occupation had been found, and he considered that it was not Roman because the Romans, wherever they made a fortress of their own *de novo*, made it more or less four-square in right lines. Maiden Castle had no rectangular lines whatever in its construction. It must be classed with the ordinary hill-top camps, but the chief feature of it was its most remarkable entrances. There were no entrances like them in any Roman camp in the world, and as far as he knew there was nothing in Europe to approach the north-western double entrance. The military engineering of the camp was simply perfect. There were strong labyrinths, and where the camp was weakest—that is, where it adjoined the main mass of the down—the entrance was protected by about seven traverses of one sort or another. The eastern end was also wonderfully strong, but not so complicated. On the whole, the labyrinthine flanking entrances and the platforms to allow of the defenders collecting and annihilating bodies of the attacking force coming in through the narrow entrances, all, as he had learnt from General Pitt-Rivers, represented the perfection of the military system of the times. When they remembered the missiles of the period—bows and arrows and sling stones—and noticed how perfectly the glacis was covered by them, they saw that these earthworks were constructed with the same engineering skill as the greatest fortresses of modern times, making allowance for the necessary changes due to arrows and sling stones being supplanted by cannon and rifle fire. Frequently a fortification was not placed actually on the crest of the hill, the object being to get rid of the dead ground—that ground which was not covered by the missiles of the defenders on the ramp. Probably the ramparts were covered with palisades.

On Friday evening the architectural section was opened at the King's Arms with a paper by Dr. Cox on "The Treatment of the Cathedral Churches of England during the Victorian Age." In the course of his paper Dr. Cox indulged in some trenchant criticism. Among those who afterwards spoke was Dr. Jex Blake, dean of Wells. It had been announced in the programme that Canon Raven, D.D., would also read a paper on "The Church Bells of Dorsetshire," but time did not suffice.

Abbotsbury.

For the 6th inst. the little fishing and agricultural village of Abbotsbury, with its monastic ruins, botanic gardens and swannery, was chosen by the Institute for visitation. The party drove down the Weymouth Road and through Upwey and Portesham. On arriving at their destination they went first to the church, the principal objects in which were indicated by the incumbent, the Rev. B. Neville. He stated that Mr. Penny, a former incumbent, considered that the north part of the church was by far the oldest, and probably anterior to the old abbey church. He pointed out the handsome carved wood Jacobean pulpit, with a sounding-board, and the reredos, also of carved wood, which he thought was put up about a hundred years ago. Two holes by which the back of the pulpit were pierced were made by bullets. There were two stone coffins outside the porch; one was found ten years ago under the porch when the church was restored, and the other, which had been about for a century, was supposed to have been brought out from underneath the abbey. In the porch was the effigy of an abbot and a little crucifix. On the outer wall of the west tower was a representation of the Trinity—the Father sitting, with the Son on the cross between His knees, and the Dove, emblematic of the Holy Ghost, at the Father's right ear. He pointed out the spot where the body of Orc was said to be buried. Orc was the steward of King Canute. He bequeathed all his property to the monastery and founded an order of canons, but in 1044 he turned them out and brought in the Benedictine monks. It was then that the monastery was really founded. There used to be a screen and a rood-loft. Mr. Micklethwaite said it looked to him that the tower was built before the nave. He expressed admiration of the reredos (date 1751), which was a thing to be cherished, the beautifully carved Jacobean pulpit, and the brass chandelier in the nave, which he suggested should be transferred to the chancel.

The Abbey Ruins.

The company then went to inspect the site and remains of the old Abbey. The Rev. B. Neville produced a plan of the Abbey Church showing the excavations made in Mr. Penny's time. He pointed out the foundation of the north aisle of the Abbey Church, which was 192 feet long, 54 feet broad, with a chancel of 27 feet, and was thus nearly twice the length of the parish church. Mr. Neville then led the party to a building which he thought was the infirmary, but which his predecessor, Mr. Douglas, took to be the Abbot's house. After viewing the undercroft they went into the Abbot's garden, and next into a building adjoining, which Dr. Hawkins said had always been described as the bakehouse and brewhouse. Mr. Micklethwaite expressed the opinion that it was the buttery, or serving place between the kitchen and the dining-room, but added that without a more complete plan it was impossible to say much about

the buildings. The members then walked to the huge monastery barn, with its series of massive buttresses. With regard to the division into two it was suggested that one barn was for the tithes and the other for the monks' own produce. Mr. Cox declared that it was all one barn. The next place visited was the Ilchester Arms Hotel, where an excellent luncheon was served. After luncheon the party climbed the hill capped by the beautifully preserved little chapel dedicated to St. Katherine. Mr. Micklethwaite briefly described the building, with its high-pitched stone roof with a lofty parapet all round, pierced with apertures to let out the rain-water. An elderly native pointed out the finger-holes and knee cavity in the wall of the entrance, by means of which the young maidens of Abbotsbury are said to suspend themselves, while, looking towards the east end, they breathe a prayer to St. Katherine to give a partner for life. As it is difficult to hang on in this position the prayer must needs be short. The approved formula of it was said by Mr. Ralls, of Bridport:—

A husband, St. Katherine,
A handsome husband, St. Katherine,
A rich husband, St. Katherine,
And a husband soon, St. Katherine.

The Chesil Beach.

The party walked a little way over the brow of the hill towards the sea, and there sat down on the grassy slope giving a fine view of the Chesil beach, the fleet, swannery and duck decoy. Professor Boyd Dawkins said that the Chesil bank travelled according to the laws of all pebble beaches on sea-shores. The pebbles were driven by the current, the set of the tide and the force of the wind from west to east, until the Isle of Portland formed a natural barrier against further moving of the mass of shingle eastward. As the pebbles travelled along the beach from west to east they became ground together more and more, and yet, contrary to expectation, the largest pebbles were at the Portland end. Although the drift from west to east was continually going on, yet the infinite changes in wind and currents combined to produce such an equilibrium that the beach was nearly always in the same position as now. He pointed out the futility of groynes running at right angles for the protection of beaches, which only caused the sea to make great ravages on the leeward side of the groyne, and advocated instead the simple expedient of uprights raised on beaches in a line with the beach, which collected and retained the shingle and soon increased the bulk of the beach. Professor Boyd Dawkins then made the remarks on Maiden Castle which have already been reported under that head. On returning to the hotel the party took tea on the lawn, fresh and cool with the playing of a fountain. At 4:15 the carriages left for Dorchester, returning by way of Hardy's Monument. The wide-spreading and magnificent view from Blackdown was much admired, embracing as it did the Devon coast to the west, the Needles to the east and the greater part of the country of Dorset.

The first rain that the Institute had experienced during their stay in Dorchester fell on Sunday, when fortunately there was no excursion to be marred by the sharp showers. In the morning the annual sermon to members of the Institute—a powerful and interesting discourse—was preached at All Saints Church by the Rev. Dr. Cox, of Holdenby. He also occupied the pulpit at Holy Trinity in the evening, and gave a long and eloquent address, which was listened to with deep attention.

Promptly at 10 o'clock on Monday, the 9th ult., the "cavalcade" left the King's Arms for Cerne Abbas and for one or two places of interest on the way.

Wolfeton House.

The first halt was made at the charming old seat of Wolfeton, the residence of Mr. Albert Bankes, a member of the local committee, who received the party with courtesy and cordiality, showed them over the house, and gave an interesting account of its history and chief features. He explained that the word "Wolfeton" came from "Wulph," the name of the first Saxon owner, and "tun," meaning house. He read Hutchins's description of the house, and distributed a number of pamphlets prepared for the bazaar held there two years ago. The entrance to the courtyard was by an east gateway flanked by large circular towers, clad in ivy, with conical stone roofs. This was the oldest part of the buildings. The house, which was bought by Mr. Bankes in 1874, was the ancient seat of the Trenchards. In rebuilding the house Sir Thomas Trenchard appeared to have incorporated some portions of an older edifice. Leading the party out to the lawn before the south front, Mr. Bankes pointed out that the outer part was rich Tudor Gothic of the time of Henry VII., and the western part Gothic of Queen Elizabeth or James I. In the former part he drew attention to the rich labels over the windows with hollow mouldings carved with fruit and foliage, and finished with spirited corbels. Up till 1742 all the windows were filled with tinted glass containing coats of arms giving almost a complete pedigree of the Trenchard family; but at present not a vestige of the Trenchard painted glass remained. There seemed to

have been four pleasaunces similar to that in which they then were, one for the ladies, another for the gentlemen, a third for the maid-servants and a fourth for the men-servants, in which they could take air and exercise in troublous times without going outside the walls of the house. The party were then conducted into the drawing-rooms and shown the ceilings adorned with an arabesque in plaster and the splendid carved doorway and chimneypieces. Tradition said that this carved work was presented by the King and Queen of Castile to Sir John Trenchard in acknowledgment of his hospitality. Early in the sixteenth century their majesties, setting forth with a great armada to surprise the King of Aragon, had scarcely left the coast of Flanders when they were encountered by a violent storm and put into Weymouth, and Sir John Trenchard, being High Sheriff of the county at the time, entertained them at Wolfeton House. Mr. Banks told the story of how the fortunes of the house of Bedford dated back to this occasion, and when in the dining-room he narrated in an interesting manner the legendary lore of the house—the portentous fall of the sceptre from the effigy of Charles I., the apparition of Lady Trenchard immediately before her suicide and the imprisonment and execution of the Catholic priest (an educated French gentleman) in Queen Elizabeth's reign. The fine tapestry on the staircase was admired, and before leaving the house the party inspected the winding staircase in the south tower of the gateway, composed of as many as forty-one steps in solid oak built into the masonry.

Charminster Church.

From Wolfeton House the antiquaries walked to Charminster Church, which, in the absence of the vicar, was described by Mr. Banks. It consisted of a nave, two aisles of equal length, and a tower 90 feet high. The original chancel, which was 28 feet long, was demolished during the Civil Wars. The present chancel was of the worst kind of churchwarden architecture, but would have to do until the parish could see their way to rebuilding the chancel on its original foundation. The nave was wide and lofty, and appeared to have been erected at the same time as the chancel arch. It had arcades of five bays on each side with a clerestory above. Mr. Banks gave a concise account of the conservative and judicious restoration recently carried out, and drew attention to the various ancient features which were brought to light in course of it, including the Norman slits in the clerestory, the staircase which led to the rood-loft, and remains of frescoes and texts on the walls. In the churchyard Lord Dillon thanked Mr. and Mrs. Banks for their kind reception of the Institute, and Mr. Banks for his interesting description of the house and church.

Cerne Abbey Barn.

The party then betook themselves to the carriages again, and continued their drive to Cerne, where the unusually fine old barn was first visited, and an appreciative account of it given by Mr. Moule. There were nine bays, each about 12 feet 6 inches long, making a total length of a little over 112 feet. There were probably five more bays at the north end, bringing the length to 174 feet; but even that was 100 feet short of the length of the great barn at Abbotsbury which they saw on Saturday when restored. The other dimensions were:—Width within, 30 feet; width without, 35 feet; height of walls, 22 feet; height of gables from eave level, 23 feet, giving a fine pitch. There was little moulding whereby to date the barn, but the whole contour, especially of the west porch, the finial thereon, the moulding of the hood of the doorway, together with the early style of the buttresses of the main building and the high pitch, seemed to give it a second-Pointed date. The roof, which fell in about twelve years ago, was a noble one, and completed an interior not to be matched in many a great church. The timbers survived in the southern part, now made into the farmhouse occupied by Mr. Sprake. He mentioned the extraordinary goodness of the masonry of flint and ashlar. He estimated the number of flints used in its construction at 172,600. It was said that the barn would originally hold the corn crop in bulk from the farm of 800 acres. Mr. Moule concluded with a glowing imaginative picture of the scene at harvest-tide in ancient days. Mr. Micklethwaite observed that the two side doors in the porches were for regulating so as to get the best natural draught according to the direction of the wind, for winnowing the threshed corn.

Abbey Church and Remains.

After luncheon at the New Inn, the company repaired to the church, which was described by the vicar (the Rev. H. D. Gundry). The architecture of the greater part of the church was in the later or debased Perpendicular style. The tower was very handsome, with its flying pinnacles under the windows and the ornamental bands round it. Hutchins said, "The entire west front, from its numerous ornaments, has an unusually handsome appearance." He called attention to the curious east window, stone screen and the wooden pulpit with canopy, bearing the date 1640, the carving of which was con-

sidered very fine. Mr. Mill Stephenson said he hoped that every care would be taken of the most interesting tintured shields in the east window. The heraldry was exceedingly good in all of them, and he trusted that they would be releaded and protected on the outside.

The party next visited that extremely picturesque relic, the so-called Abbey gateway, and then St. Augustine's Well, to which tradition assigns a miraculous origin and marvellous curative virtue.

The Cerne Giant.

But the chief "lion" of Cerne is beyond question the Giant, and to this the party now addressed themselves valiantly to climb. Having seated themselves somewhat in the form of a halo around the giant's head, the company listened to a few words from Mr. Green, who was able to throw little light on its origin. Then Professor Boyd Dawkins observed that he was in blank ignorance about the date of "the Giant." It was, however, there in the midst of what was in the Bronze Age and the prehistoric Iron Age a centre of dense population. Above them were a hut circle, a settlement, a camp, a tumuli, showing that there was once a large population scattered over the downs. The whole of the hill slopes over against them were perfectly covered with similar remains and ramparts which might or might not be enclosures. Nine out of ten of the tumuli which had been dug really belonged to the Bronze Age. By its surroundings then that figure was in a position which would make one pause before assigning it to any particular modern time. Figures of that class were not altogether unknown in sculptures belonging to the Bronze Age, and which had been found in Scandinavia ranging down to the early Iron Age. Therefore he thought it by no means improbable that the great figure on Cerne Hill might really belong to that remote time. Professor Boyd Dawkins added some interesting observations about the habitation of the chalk downs in old days, while the low land was either forest or morass. Mr. Moule narrated some folk-lore about the Giant: One legend stated that it was a "real live giant," who was caught napping and, by the united efforts of all Dorset, pinned down as Gulliver was by the Liliputians. Then his shape was cut out in the turf, so that they saw an exact presentment of him. Another story was that it was a caricature of the last abbot of the abbey. The Dorset Field Club had been specially requested by the owner, General Pitt-Rivers, not to come near the giant or say anything about him until he could have time to dig about the figure, find out something more, and have a paper to read to them. Professor Boyd Dawkins inquired about the probability of ancient enclosures having been behind the abbey. Mr. Moule answered that the undulating ground was said to be the pleasaunce. It was still called "Beauvoir." He pointed to the delightful old house of Upcerne, which was built out of part of the abbey ruins.

Wrackelford House.

The party then descended the hill and started on the homeward journey. On the road they made a detour to visit Wrackelford House and accept the kind invitation of Mr. and Mrs. Alfred Pope to afternoon tea. The company had a most hospitable reception, and before leaving the pleasant house and grounds Lord Dillon, on behalf of the Institute, expressed his warm appreciation of the kind entertainment given them by Mr. and Mrs. Pope. Mr. Pope, in acknowledging the expression of thanks, spoke with pleasure of the visit of the Institute. They had good archaeologists living in the neighbourhood, but they were always glad to have fresh light thrown upon their local antiquities.

In the evening, when Dr. Cox presided at the sectional meeting, Sir Talbot Baker gave an account of the House of the Vestals in the Forum at Rome and the discovery of Anglo-Saxon coins in the excavation of it. A vote of thanks was passed to him on the proposition of Dr. Cox, seconded by Professor Clark. Then the Rev. A. D. Hill, of Downton, described the interesting discovery of an Anglo-Saxon church at Breamore, Hants, and was thanked on the proposition of Dr. Cox, seconded by Mr. Micklethwaite.

Research at Maiden Castle.

Professor Boyd Dawkins, referring to Maiden Castle, said he thought it most desirable that the wonderful fortresses for which Dorset was almost unique should be dug. He should be exceedingly glad if, instead of their having theories propounded to them as to the age of some of those camps, they could apply the pickaxe and shovel to reveal their true age. He for one would be glad to co-operate in any such work. It would be a fitting mark of their visit to Dorchester if they could help the Dorset Museum, adding somewhat to its contents by proving the date of some of those camps.

Lord Dillon moved the following resolution:—"That this meeting of the Royal Archaeological Institute heartily approves of the proposition made by Professor Boyd Dawkins for the systematic investigation of Maiden Castle, believing that such a step, carefully undertaken under his direction, will be of the first importance towards the elucidation of its earliest history."

Dr. Cox seconded, considering that they should try to imitate what General Pitt-Rivers had done elsewhere. It would settle the matter once for all. Mr. Micklethwaite said he thought that the Institute had enough to do already. Chancellor Ferguson asked whether they were prepared to put their hands in their pockets. Dr. Jex Blake: Is it an abstract proposition, or do we really mean to go to work? Mr. Mill Stephenson: The Institute does not do the work, but merely signifies its approval of Professor Boyd Dawkins's scheme. The motion was then put and carried *nem. con.*

On the 10th, on the occasion of their last excursion in the neighbourhood of Dorchester, the Institute took a different direction, going east and north, first to

Puddletown Church.

Here the party were received by Lieutenant-Colonel Brymer, M.P., and the vicar (Rev. F. E. Freeman). The church is one of the most interesting and beautiful that the Institute have visited in Dorset, and is replete with objects of archaeological value in architecture and furniture, monuments and heraldry. A description of the church was given by Mr. E. Doran Webb, F.S.A. It is late Perpendicular in style. The picturesque old western gallery, with open balusters and carved coat of arms, is Carolean, bearing date 1635, and the pews in the nave and the altar rails are of the same date. The gallery and pews in the north aisle and chapel are Georgian. Mr. Webb hoped that the western gallery would be left, and that none of the seats would be moved. Attention was drawn to the nicely carved wooden roof, with an elaborate cornice. There are five bells in the tower, one being cracked, and Mr. Webb said he trusted it would not be recast, as the value of the bell metal so obtained would not make amends for the loss of a valuable bit of history. Lord Dillon spoke upon the interesting collection of monuments, and expressed especial admiration of the marble recumbent effigy of a member of the Martin family lying under a stone canopy, which he said was peculiar and singularly fine. Mr. Webb said he thought the font was early thirteenth century. The character of the ornamentation was most remarkable.

Athelhampton Hall.

The party well-nigh went into raptures with the old-world charms of Athelhampton, or Adminston Hall, to which they were next introduced. Mr. A. C. de Lafontaine, the owner, received the party at the door, but delegated to Mr. Moule the duty of describing the house. Mr. Moule's description was of the briefest. The years 1487 and 1502 were variously assigned as the date of the house. The gatehouse, taken away forty or fifty years ago, was an immense loss, archaeologically speaking. Within the house Mr. de Lafontaine's careful and tasteful repairs spoke for themselves. Of the old features, besides the untouched roof with its remarkably bold cusps, might be noted the original hall doors, one *in situ*, and the curious stone and oak stairs. The garden front had been admirably completed by Mr. de Lafontaine. The company then entered the house and inspected the principal rooms, especially the fine hall, with its high chimney-piece and gallery and the library upstairs, with a plaster ceiling moulding in arabesque and the walls handsomely wainscotted. But on such a sunny summer day the surroundings of the house were more attractive even than the rich and beautiful interior. The visitors sauntered from one pleasure to another, admiring the walled-in gardens of various sizes and shape, rectangular or round, communicating with one another by archways and flights of steps. Amid well-mown lawns and bright and fragrant flower-beds are set fountains and fishponds, in which the gold fish gleam with a rich metallic lustre as the sun strikes them. The charming old dovecot, with its soft-cooing denizens, the statues and the gorgeous-plumaged parrot chained to its stand are among the details that enrich a picture that will not soon be forgotten. Wandering through this veritable palace of art it was not easy to remember that one was living in the last decade of the nineteenth century, instead of full 400 years ago, when the scene must have been little different. The members of the Institute seemed to feel the witchery of the place, and showed themselves far more loath than usual to respond to the summons of the director's horn and the secretary's equally importunate whistle. At last, however, the spell was broken, and the hindmost stragglers whipped in. When the party were reassembled in front of the house Lord Dillon expressed to Mr. de Lafontaine their warm thanks for admitting them to his lovely abode, and congratulated him on his successful preservation of so many interesting and beautiful things. Mr. de Lafontaine, responding, observed that Lord Dillon's kind words would encourage him to go on with the work of restoration as well as in his power lay.

Milton Abbey.

The carriages then drove to Milton Abbey. The undulating and well-timbered park in which the old abbey and the adjoining house stand was much admired. Luncheon having been taken the party entered the abbey church. It is said that the

abbey was founded in 938 by Athelstan, grandson of Alfred the Great, to commemorate his victory over the Britons at Brunanburh, in Devonshire. It was founded originally for secular canons, but Dunstan of Glastonbury expelled the canons and established Benedictine monks in their stead. On the dissolution of the monasteries Henry VIII. gave the abbey to Sir John Tregonwell. The church was made the parish church of Milton Abbas till the last century, when it was by Act of Parliament desecrated and became private property. Mr. Doran Webb described the church, calling attention to the beautifully vaulted roof in Ham Hill stone, the high altar, the windows with their heraldic glass, the monuments, and especially the "tabernacle," the greatest treasure which the church contains. It is of wood, made in four storeys, richly carved and painted. Its use was to hold the pix in which the Eucharist was reserved for the communion of the sick and dying. It is now attached to the west wall of the south transept beneath the triforium, but originally it was probably suspended above the high altar. To its old position it has been proposed to restore it, but Mr. Webb advised that it should be allowed to stay where it is.

Concluding Meeting.

Lord Dillon, president of the Institute, then took the chair, and the business of the concluding meeting was begun.

Bingham's Melcombe.

Passing through Ansty the party next went to that most out-of-the-world seat, Bingham's Melcombe manor-house. Here they were hospitably received and entertained to tea by Mr. and Mrs. Bosworth Smith. Mr. Moule made a few remarks been published in the *Dorset County Chronicle* during the past few years.

about the house, of which a description has more than once Mr. Doran Webb considered that the main part of the house was Elizabethan, with Queen Anne insertions.

Mr. Moule stated that Mr. Ponting, the diocesan architect, who had been there lately, assigned the gatehouse to the reign of Edward II., chiefly on account of the construction of the beams in the roof, which were undoubtedly of that time. The gable containing the oriel window, with the deeply-sculptured coat-of-arms and the beautiful work of the corner shafts, was the most picturesque feature of the house, and probably Marian. The beautiful bowling-green and yew hedge, supposed to be of the time of Henry VIII., the arbour, the fishponds and the shaded ways to them and up the stream were of the utmost loveliness and gave completeness to the place; and all, he said with emphasis, were old features, and had been there from generation to generation, from century to century. After enjoying tea, and taking a ramble through the house and grounds, which fully confirmed Mr. Moule's verdict as of "the utmost loveliness," the company gathered in the courtyard, where Lord Dillon was once again the spokesman of the Institute, in acknowledging a kind reception and generous hospitality. Mr. Bosworth Smith, in reply, said that next to the pleasure of owning a beautiful old house came the pleasure of showing it to an appreciative body such as they. A few minutes were spent in the porch, and then the homeward drive was begun.

Valedictory.

This concluded the stay of eight days made by the Institute in Dorchester and the neighbourhood. On the 11th a party of upwards of thirty members embarked at Weymouth for Jersey, to accept the invitation of the Société Jersiaise to devote Thursday and Friday to excursions in the island under the guidance of the Society. Thanks to the careful arrangements, ably carried out, to the co-operation and kindness of the local friends, and to the most favourable weather, the Dorchester meeting has been, as the members of the Institute declare, a perfect success, and one of the most enjoyable on record. We ought not to omit to mention that this happy result has also been in no small measure contributed to by the admirable way in which the large company have been catered for by Mr. and Mrs. Bilham, at the King's Arms. The accommodation, the table, the posting arrangements have all been of the highest excellence, and have evoked general expressions of satisfaction. Of Dorset, its antiquities, its beauties, its hospitality and good-fellowship, the Royal Archaeological Institute have received fresh and most favourable impressions, not easily to be effaced.

THE BIRTHPLACE OF JOHN KNOX.

MR. HALDANE'S cocksure remarks in the House of Commons the other night, says the *Glasgow Herald*, indicate very plainly that he at least is quite certain of the place where John Knox was born, and that that place is the latest of the three advocated by "authorities," Morham, one of the least, if not the very least of the parishes in Scotland. Strange if one of the greatest of Scotsmen should hail from one of the meanest of Scottish parishes. There are grave doubts as to the accuracy of Mr. Haldane's opinion—we do not say judgment. Three places have been claimed as the birthplace

of the great reformer, (1) Giffordgate, in the Nungate of Haddington; (2) the village of Gifford, four miles to the south of Haddington, the exact place being Giffordgate, described in the minutes of the Road Trustees of the parish of Yester in 1793 as distant 406 yards from Gifford Cross; and (3) the parish of Morham. The late Thomas Carlyle, whose wife was a descendant of John Knox, was in favour of the place first named—Giffordgate, Haddington—and left instructions to his trustees to have a memorial erected. In 1881 a tree—an oak, which is now flourishing—was planted by Miss Watson, the proprietress of the ground on which the famed house is supposed to have stood. After the ceremony of planting the tree Colonel Davidson spoke of his last interview with the sage, who was then very near to the hereafter. He said:—

"After a touching allusion to the grave of his loyal wife, Mr. Carlyle said he had a request to make, namely, that I would get a tree planted to mark the site of the house where Knox was born, so that it might be seen from the churchyard. I said, 'A tree will not last long.' 'An oak,' he replied, 'will last a long time.' 'Yes,' I added, 'perhaps as long as the world, which seems to be getting into its death throes.' 'Ah,' he said, 'the world will last a long time yet.' To show the necessity of planting this tree Mr. Carlyle went on to say that many years ago some ladies, visitors at Amisfield House, wishing to see the spot where the great Reformer was born, wandered into the Nungate towards the Giffordgate, and, accosting an old woman, asked if she could show them Knox's house. 'What's yur wull?' said the old woman, who was somewhat deaf. 'We want to see John Knox's house.' 'John Knox's house; that's it ower there, and yon John Knox himsel' sitting at the door.' Having told this story in his own inimitable doric, Mr. Carlyle fell back on his pillow and laughed till the couch shook under him."

In 1858 the late Mr. John Richardson, procurator-fiscal, Haddington, read a paper before the Society of Antiquaries of Scotland, which was printed in their "Proceedings," vol. iii. part i. The paper was entitled, "On the present state of the question—'Where was John Knox born?'" At this time Morham was not a candidate for birthplace honours, and Mr. Richardson was entitled to say that it was admitted on all hands that Knox was born either in the village of Giffordgate, a suburb of the town of Haddington, or in the village of Gifford, four miles distant from that town. Dr. McCrie had summed up in favour of Gifford, (1) on the authority of Beza, a contemporary of Knox, who designates him "Joannes Cnoxus, Scotus, Giffordiensis," which Dr. McCrie thought "evidently means that he was a native of the town of Gifford;" and (2) on the authority of Spottiswood, another contemporary, who says he was "born in Gifford, within Lothian." Other authorities, quoted by Dr. McCrie on the same side, were David Buchanan, who wrote in 1644; Matthew Crawford, in 1732; and Woodrow; but, according to Mr. Richardson, "these three are merely followers of the other two, and quote no other independent authority or cause of knowledge." On the other side are Archibald Hamilton, a zealous Roman Catholic, Knox's countryman, contemporary and acquaintance, who in his "Dialogue," &c., published in Paris in 1577, says he was born "in Haddingtona oppido in Laudonia," in Haddington, a town in Lothian; and another Scotsman, Laing (Mr. Richardson does not mention the name), a Roman Catholic, who in his book "concerning the life, &c., of the heretics" of his time (Paris, 1581) affirms the birthplace to have been "Prope Haddingtonam," near Haddington. Hamilton is understood to have been personally acquainted with Knox, and knew his parents also. Beza was a foreigner, and might not know all the peculiarities of East Lothian topography. Dr. McCrie, according to Mr. Richardson, was in favour of Giffordgate, Haddington, till he found among Lord Wemyss's titles a charter to "William Knox in Morham, and his wife," in 1598, of certain lands in "the territory of Nungate," and "having found by inquiring at the descendants of this William Knox and his wife that the Reformer was no relation of theirs, he rejects the authority of tradition in favour of Giffordgate as the place of his birth, and sums up in favour of the village of Gifford." Giffordgate belonged to the Marquis of Tweeddale and adjoined the property of the Earl of Wemyss, and Mr. Richardson shrewdly argues that because a certain William Knox had lands in the one, it does not follow that there was no one of the same name in the adjoining village. Tradition favours a certain spot in the Giffordgate as the birthplace, and the late Mr. James Watson, writer, Linlithgow, proprietor of the ground, has "instruments" dated in 1607 and 1611, in which certain "butts" of land are described as bounded by "Knox Walls," thus showing that the name of Knox had been remarkably connected with it. Again, Knox was educated at the Grammar School of Haddington, and Mr. Richardson infers from that that he did not reside four miles away. Still further, there is no evidence that a village called Gifford existed at the date of Knox's birth. On the contrary, at that time and till long after his death the parish of Gifford was called Bothans, and the village of the parish was likewise

so called. It is evident from Pont's map of Lothian, prepared about 1620, that no such village as Gifford or Gifford Hall then existed. These are the main points of Mr. Richardson's case for Giffordgate, Nungate of Haddington. The distinguished antiquarian, Dr. David Laing, made inquiries after the reading of Mr. Richardson's paper, and found that Knox was admitted a burghess of the city of Geneva, and in the register he is called, of course upon his own authority, a native of Haddington—"JEHAN CNOXE . . . NATIF DE HADINGTON EN ESCOSSE." Dr. Laing adds:—

"This, I presume, means the town or immediate suburb of Haddington, and extinguishes any claim for the village of Gifford, even if it could be shown that such a village was then in existence. Mr. Richardson has clearly established the fact that the suburb of Haddington called Giffordgate was so known during the sixteenth century, and that some houses there till a recent period retained the name of Knox's Walls. This removes the apparent discrepancy of Beza's styling him 'Giffordiensis,' and yet connecting him with Haddington. Knox himself in a foreign land—if Edinburgh, for instance, instead of Haddington, had been the place in question—would never have named a locality such as the Cowgate or Canongate, but the town itself, as the place of his nativity."

In 1860 the Rev. Samuel Kerr, minister of Yester (Gifford), issued a reply to Mr. Richardson, and put forward the claims of Gifford to being the birthplace of the Reformer. The styles of the lawyer and the clergyman are easily distinguishable in the two papers. Mr. Kerr says none except Hamilton assigned any other birthplace than Gifford till Knox's body had been two hundred years in the grave. The evidence of David Buchanan he considers of great importance, because he was contemporary and probably acquainted with the daughters of Knox, as well as with many who had known him in his declining years. This supposition, it may be remarked, is not strengthened by any evidence. The Gifford minister further objects to Laing's expression "Prope Haddingtonam" as favouring Giffordgate, Haddington. "Prope" means near, not very near or close to, and would not be applied in the case of places separated only by an "insignificant stream." Hamilton's "mistake" Mr. Kerr explains satisfactorily to himself on the principle that "Haddington being both the county town and the most considerable in the district, would naturally, in common conversation or by common report, obtain the credit or the discredit due to the surrounding neighbourhood as well as that which belonged properly to itself." Curiously enough, Mr. Kerr has not mentioned in support of his theory the fact that the shire is Haddington, and that people might readily in the days of Knox, as at the present time, talk of a Haddingtonshire man as a Haddington man. Later on he makes use of this argument in the Geneva extract. Mr. Richardson's argument that Knox's parents being "obscure" and poor, the Reformer would not have been sent to a grammar school four miles distant, is hardly worth refutation. Why, he was sent to the University of Glasgow. Mr. Kerr brings forward Sir Walter Scott as witness in favour of the existence of Gifford at a time contemporary with Knox. In "Marmion," canto iii. stanza 1, the following lines occur:—

The noon had long been passed before
They gained the height of Lammermoor;
Thence, winding down the northern way,
Before them, at the close of day,
Old Gifford's towers and hamlet lay.

Beza's use of the word "Giffordiensis," and Spottiswood's "Gifford within Lothian," are certainly difficult to get over. Again, it may be asked, why Gifford Gate if there was no Gifford? The most natural deduction surely is that people on their way to Gifford passed through Giffordgate, and as a matter of fact they do that yet.

So far we have given an outline of the minister's claims for the village of Gifford. Last of all come the schoolmaster's claims for Morham, the spot favoured by Mr. Haldane, M.P. Mr. David Loudon, for a number of years teacher at Morham, wrote a history of the parish (W. Sinclair, Haddington, 1889). After having startled antiquarians by the announcement that in this small parish, whose "name in all probability is unknown to the bulk of Scotsmen," was born he who "in his lifetime never feared the face of man," Mr. Loudon proceeds to explain Beza's "Giffordiensis." "Beza had heard Knox talking of Sir John de Gifford of Yester, who married Euphemia, daughter of Sir Thomas Malherb, otherwise Sir Thomas de Morham—the last heir male of the manor of Morham. This Euphemia, on her marriage with Sir John de Gifford, transferred to him the manor of Morham along with other estates, and henceforth, as was the common practice then (and in some districts is so still), the name of the estate and the name of the proprietor became synonymous terms, so that it would as frequently be called 'Gifford' as 'Morham.'" The "Gifford within Lothian" is held as of no account owing to the inaccurate statements made elsewhere by the writer. It appears that Knox, when pleading for some favour from James

Earl of Bothwell, wrote :—"My great grandfather, gudeschir, and father have served your lordship's predecessors, and some of them have died under their standards." Mr. Loudon argues that the only way this could have been done was as tenants of his farm of Mainshill, in the parish of Morham. The tombstones in Morham churchyard prove conclusively that there were Knoxes "fermers in Mainshill" for a long time after the birth of the Reformer. Replying to Mr. Richardson's argument in favour of Giffordgate, Haddington, based on the titles of Mr. Watson, Linlithgow, mentioned above, Mr. Loudon says :—

"The said William Knox died in October, 1607—the very year in which the first Sasine is dated—and his testament datative was produced by his widow on behalf of their children, William, George, James and Bessie—minors. James Knox, brother of the deceased, is named as a debtor; and the personal estate, chiefly in farm stock, is valued at 1,359*l.* Does not this clearly show that the first Knox of Haddington came from Morham, and that his relatives were 'fermers'?"

Mr. Loudon fortifies himself with a tradition. He tells how in 1883 "an aged patriarch named Neilson, from Dunbar, accompanied in a gig by one Ferguson, from New York," called on him. It is not stated whether or not this Ferguson was a friend of Mark Twain's. "The old worthy seemed delighted and hastened me to the knowe where Knox's house stood, and said he was taught from infancy, as were his father and grandfather before him—all born on Mainshill—to look with a 'reverential pride' on that spot, as it was there our Scottish reformer, John Knox, was born." The Rev. William Whitfield, an antiquarian of some note, formerly a minister in Dunbar and now in Canada, backed up Mr. Loudon. Dealing with Knox's conversation with the Earl of Bothwell, he argues that Knox's paternal ancestors were tenants of Mainshill, and his maternal ancestors, the Sinclairs, were tenants of Northrig, both in the parish of Morham, and "in the charters passed the Great Seal of Scotland and kept in the Register House, Edinburgh, we find abundant proof of the possession of these lands by Bothwell's ancestors." Thus far we have given an outline of what appears to be the more important evidence bearing on an important incident in Scottish history.

THE ORDNANCE SURVEY.

THE report of the progress of the Ordnance Survey to March 31, 1897, states that, while all cultivated districts in England and Wales were surveyed before 1890 on the 1-2,500 scale, with the exception of Lancashire and Yorkshire, the plans for all the cultivated districts of Lancashire and Yorkshire have since been published. The revision of the maps on the 1-2,500 scale was sanctioned in 1886, but the actual work of revision was not begun until 1894. This is attributed to the necessity of resurveying those counties which had been originally surveyed on the 6-inch scale. Some delay was also caused by the revisions which had been in progress in London, Plymouth, Glasgow and the Tyneside towns, but the 1-2,500 revision has now been taken up in Middlesex, Essex, Kent, Surrey, Sussex, Hampshire, Buckinghamshire, Hertfordshire, Northumberland, Nottingham, Cheshire, Derbyshire, Glamorganshire, Durham and Westmorland. The area revised during the year 1896-97 was 4,623 square miles. The rate of progress, it appears, has varied greatly, progress having been slow where great changes have taken place, as in the neighbourhood of London, and relatively rapid in the agricultural districts. Publication of the revised plans is proceeding, and 3,567 square miles have been published during the year. It is estimated that the arrears will be made up by 1910, and the intention is expressed that after that has been done no sheet shall represent a survey or revision more than twenty years old. Maps on the 6-inch scale have been published for all England and Wales. The new series 1-inch map is published in two forms—(1) outline and contours, this map being now completed, and combined maps published also for Brighton, Derby, Gloucester and Cheltenham, Plymouth, Nottingham, Chatham and Winchester; (2) hill features, the publication of which will, according to existing arrangements, be completed in 1902. The experiment is being made of having some sheets of this map engraved by the trade in order to accelerate the progress of the work. The revision of the 1-inch map is being carried out independently of that of the larger scale maps, and it is intended that all sheets should be annually brought up to date as regards railways, canals and important public works. During the revision certain alterations are being made in this map so as to bring it more into harmony with military requirements without injuring its utility for civil purposes. At the instance of the War Office an experimental 1-inch map in colours has been prepared, by transfer of zinc, of most of the district south of the Thames, and the publication has been sanctioned by the Treasury. The revision of the map issued on the scale of four miles to an inch is to follow immediately that of the 1-inch map. The plans of all towns entitled to a large scale survey have been published, and the

survey of London on the 5-foot scale has been revised and extended.

Details are also given in the report of the progress of work with regard to Scotland and Ireland and the Isle of Man. In the case of both Scotland and Wales the corrections of place-names which have been found necessary have been found to be comparatively few. Reference is made to the entire change that has been made in the system in force for the sale of the maps to the public. No comment is made on the degree of success resulting from this change, but the list of the total values of the maps sold each year show that, while from 1889 to 1893 the annual value varied between 13,100*l.* and 13,700*l.*, increasing to 14,903*l.* in 1894 and 15,497*l.* in 1895, the amount reached 17,715*l.* in 1896-97. Index maps are appended to the report showing the periods which have elapsed since the dates of the surveys of the various counties and other particulars as to revision and publication.

FOLK-LORE OF THE HOUSE.

THE late Rev. Walter Gregor, LL.D., who was an accomplished inquirer into folk-lore, died in February last while engaged on that work. The following records relating to the customs and traditions in Galloway, of which the dwelling-house is the subject, were found among his papers :—

Kirkmaiden.—When the foundation of a house is laid, the workmen are entertained with whisky. This whisky is called the "funin pint," i.e. foundation pint.

When the carpenters begin to put on the roof of a house, they receive at times whisky. This is called the "reefin pint," i.e. roofing pint. (Informant a carpenter.)

Dalry.—It is unlucky for one to build a house to live in.

Kirkmaiden.—My informant has heard it said that it is unlucky for one to build a house to live in.

Dalry.—It is not lucky for one to enter for the first time by the back door a house he (she) is to live in.

Balmaghie, Kirkmaiden.—The floor of the dwelling-house must never be swept towards the door, but towards the hearth.

Kirkmaiden.—The hearthstone is accounted the most sacred part of the dwelling-house.

Kells.—When Kirkdale House, in the parish of Anwoth, was built, the man that laid down the first load of stones for the building of it was hanged for the murder of a woman whom he had led astray, and the mason that laid the first stone of it was killed in the course of its erection. The common explanation of these fatalities was that the owner of the house had gained his fortune by unjust means.

Kenmure Castle, in the parish of Kells, was planned to be built on an island in Loch Ken, and a quantity of stones was laid down for its building. During one night before the work was begun they were all taken away and laid down on the site the castle now holds. (Told in Balmodellan.)

In a holm on the river Ken, near Kenmure Castle, there is a large block of stone. It was thrown from Cairne Edward by the devil to destroy Kenmure Castle. He put too much force into his cast, and the rock went over the castle and fell on the holm beyond it.

Rerrick.—When the old church of Rerrick was being taken down the aunt of the wife of the man that had contracted to do so remonstrated with her for allowing him to undertake the work. He or another of the workmen, she said, would be killed. A beam fell upon him and injured him.

Kirkmaiden.—In flitting into a house that has been left vacant by another, no one enters it without first casting into it a living creature, commonly a cat or a hen. If "ill has been left on the house," it falls on the animal that is thrown into it. It dies, and the lives of those that are to dwell in the house are spared.

A family at Aachliach, when removing, bore a grudge against those that were to occupy the house after them. They swept the hearth and the house clean, and put on "a stone fire." Something had been forgotten in the house, and a daughter returned to fetch it. The "ill that had been left on the house" fell on her. She became a cripple, and for many years was able to walk only on crutches.

Rerrick.—In going into a house from which another person or family has removed, it was usual to cast into the house a living creature, as a cat or hen, before any of the family entered.

If one, on leaving a house, had a grudge against those that were to live in it, the house was swept clean and a fire of stones and green thorn was placed on the hearth.

A family of the name of Burnet went into a house at Hole-house, from which had gone out another family that bore an ill-will against the new tenants for putting them from the house. The fire of stone and green thorn had been placed on the hearth. The usual precaution of casting in a living creature had been omitted. The youngest son was the first to enter the house. "He did nae guid aifter," i.e. he fell into weak health. My informant has heard the young man's brother tell the story.

My informant's daughter was removing from a house. To

leave the house as neat as she could for those that were to occupy it after her, she swept the floor of the house, lifted the sweepings and cast them out. The man that was to inhabit the house was present. Seeing what she did, he called out, "Ye —, why did ye soop awa ma luck?"

"THE BERMUDAS," STRAND.

THE mesh and labyrinth of obscure alleys and lanes running between the bottom of St. Martin's Lane and Bedford Street towards Bedfordbury were swept away by the besom of improvement in 1829, when Trafalgar Square was begun, never to be ended. In Elizabeth's or James's time, gallants who had cruised in search of Spanish galleons wittily nicknamed these straits "The Bermudas," from their narrow and intricate channels. Here the valorous Captain Bobadil must have lived in Barmecidal splendour and have taught his dupes the true conduct of the weapon. Justice Overdo mentions the Bermudas with a righteous indignation. "Look," says that great legal functionary, "into any angle of the town, the Streights or the Bermudas, where the quarrelling lesson is read, and how do they entertain the time but with bottled ale and tobacco?" How natural for Drake's men to give such a name to a labyrinth of devious alleys. At a subsequent period the cluster of avenues exchanged the title of "Bermudas" for that of the "Cribbee Islands," the learned possessors corrupting the name into a happy allusion to the arts cultivated there. Gay, writing in 1715, describes the small streets branching from Charing Cross as resounding with the shoeblacks' cry, "Clean your honour's shoes?" Improvements were made in 1829-30, when the present covered walk with a glass roof, leading from West Strand to St. Martin's Church and inhabited chiefly by German toymen, was built and named after Lord Lowther, then Chief Commissioner of the Woods and Forests. The Strand was also widened and many old tottering houses were removed. Porridge Island was the cant name for a paved alley near St. Martin's Church, originally a congeries of cookshops erected for the workmen at the new church and destroyed when the great rookery there was pulled down in 1829. It was a part of Bedfordbury and derived its name from being full of cookshops, or "slapbangs," as street-boys call such odorous places. A writer in *The World* (1753) describes a man like Beau Tibbs who had his dinner in a pewter plate from a cookshop in Porridge Island and, with only 100*l.* a year, was foolish enough to wear a laced suit, go every evening in a chair to a rout and return to his bedroom on foot, shivering and supperless, vain enough to glory in having rubbed elbows with the quality of Brentford.

The Nude in Greek Art.

SIR,—I have been very much interested in the battle of ink which has been taking place between "A Lady Artist" and Mr. Ronald Kelly. My sympathy, of course, is with the lady, otherwise I should never have earned my well-earned title of "a lady's man." It would appear that Mr. Kelly is quite upset. I am afraid from his letters that he would like to see all our statues draped in some (of course) thick material, so that under no circumstances could any line of figure be seen. Fancy the shame he must feel when he takes his walks abroad and comes face to face with some sturdy little rascal enjoying his or her dip in the village stream. Oh, the horrors of the sight, the burning blush that must come to his fair cheeks, when possibly there may be two, and not both of the same sex. The thought is too horrible, Mr. Editor, to contemplate. Mr. Kelly's plea is for the children. The natural, healthy-minded child would not for one moment have the thoughts pass through his or her head which your correspondent seems so much to fear, but that which has been created beautiful would receive that reverent admiration which is not the sole possession of a "lady" or "gentleman artist."—I am, Sir, your obedient servant,

IGNORAMUS (on art matters).

SIR,—I am much indebted to you for your fairness in giving publicity to my second communication, and was hoping that I should not have to trouble you again for a little of your space. I feel all the more loath to ask you to spare it on my behalf, not wishing to deprive "A Lady Artist" of her "last word." However, her concluding letter may well be considered as such, inasmuch as I abstain from making further propositions, but am merely writing by way of reply, and especially to explain an evident misunderstanding.

She impugns my conduct as a gentleman. What I have said respecting feminine artists was intended to apply to them collectively, or as an instrument. In replying to your

correspondent I recognised her as an individual—a female—and, therefore, was "more polite" as she expresses it; unfortunately "A Lady Artist" appears to be unable to appreciate the difference.

It is a pity she should have so much recourse to sarcasm—that weapon of the weak. It is not clever, neither is it convincing.

The old stock argument that the study of, and the portrayal of, nude figures is to be encouraged because "suggestion is worse than reality"—so to speak—will not stand, for if the principle were admitted we might as well exist in a condition which civilisation would scarcely tolerate, it being possible to be "educated-down" to anything—unfortunately far more easily than *vice versa*.

Your correspondent is quite right; I have a "bee in my bonnet" as she terms it, and the sooner that "bee" is crushed the better for all.

Her last letter is a sensible one—always excepting her "altogether" nude ideas, for which she is to be sincerely pitied.

Permit me, in conclusion, to again thank you for your courtesy, and to subscribe myself your very obliged servant,

RONALD KELLY.

16 Southampton Street, Fitzroy Square:

August 30, 1897.

[The correspondence cannot be continued.—ED.]

GENERAL.

The **Surbiton Urban Council** have received twenty-seven sets of designs for the new offices. The selection will be announced at the October meeting.

A **Newcastle** shipowner, Mr. John Hall, has offered to give 100,000*l.* for the erection of the Newcastle Royal Infirmary, on condition that a site is obtained on the Castle Leazes or Town Moor recreation-ground.

The **Dean and Chapter** of Canterbury have erected in the crypt of the cathedral a tablet "To the beloved and honoured memory of William Archibald Scott Robertson, M.A., hon. canon of this cathedral, as a mark of gratitude to one who ungrudgingly devoted to the service of the cathedral his faithful labours and his abundant antiquarian knowledge."

The **Autumn Exhibition** in Liverpool contains 1,342 works, an increase of about 100 over last year. Several pictures from the last Academy exhibition are to be seen. The Queen has lent Lady Butler's *Roll Call*.

Owen Jones Prizes have been awarded to the following competitors:—William F. Blagg, School of Art, Chelsea—design for wall-paper; Helena R. Dow, School of Art, Glasgow—design for wall-paper and frieze; Robert Paterson, School of Art, Glasgow—design for a carpet; Herbert D. Richter, School of Art, Bath—design for wall-paper; Bertha Smith, School of Art, Bloomsbury—design for wall-paper and frieze; John Wadsworth, School of Art, Macclesfield—design for carpet.

The **Coronet Theatre** in Notting Hill is the latest proposed addition to the numerous metropolitan buildings of its class.

Pluscarden Priory, near Elgin, has been purchased by the Marquess of Bute from the Duke of Fife, and is to be restored.

The **Vicar** of Stratford-on-Avon is endeavouring to raise 5,000*l.* for the further restoration of the parish church (Shakespeare's church). The restoration of the chancel has been completed, and it is now proposed to restore the nave.

Mr. Bodley, A.R.A., has prepared a design for an elaborate altar and super-altar in St. Helen's Church, Abingdon, which, with marble flooring in the lady chapel, will be the memorial of the late vicar.

Sir A. W. Franks's Bequest to the British Museum will be available, as the condition of a remission of probate duty is agreed to by the Treasury.

Mr. A. E. Brockbank has opened an exhibition of his drawings and paintings in Holland at his studio in Liverpool.

M. Munkacsy, the Hungarian painter, is recovering at Bonn from an illness which he has had to bear for ten months.

A **Tower** is to be erected on Castle Hill, Huddersfield, as a memorial of the Jubilee. Thirty-two sets of designs were submitted in the competition. A design by Mr. Isaac Jones, of Herne Hill, S.E., has been placed first; one by Messrs. Haigh, of Huddersfield, comes second; and the third is by Mr. W. R. Watson, of Glasgow.

The **Marquis of Zetland** has contributed 100*l.* towards the erection of a new church in connection with the charge recently sanctioned by the Church of Scotland in Grangemouth.

A **Congress of Architects** is being held in Brussels. Professor Aitchison, A.R.A., represents Great Britain.

Mr. W. H. Bidlake, M.A., will again be the instructor in architectural history and architectural design at the Birmingham Municipal School of Art. His assistants are Mr. H. T. Buckland and Mr. A. T. Dunn.

The Architect.

THE WEEK.

It is sometimes difficult to decide how far officials in Government and municipal offices should be allowed to engage in business of another sort after office hours. Civil servants were enabled to open stores in London, because it was supposed they were endeavouring to aid their fellow clerks to buy goods at cheaper rates than was possible when dealing with retail shops. It was not foreseen that a business would arise on a colossal scale in which the original principle was set aside, and profit-making for a few people became the sole aim of the philanthropic enterprise. A Parliamentary inquiry could not now fail to have for its result a decree against the employment of Civil servants in conducting establishments which have no higher aim than the humblest shop in the Borough. But there are cases of dual employment where finance alone must not be considered. In Dublin there is a standing order of the Corporation which declares that no officer of the Council should be at liberty to concern himself in the ownership, control, or management of any business or trade. But it was discovered lately that two officers of the public health committee were directors of a building society, and therefore were not unlikely to have to consider plans submitted for approval on the part of the society. When the case came before the Corporation it was found that twenty-three members approved of the practice in spite of the standing order, while twenty-five decided to uphold the order. The reason given was that it was preferable to have Corporation officials devoting themselves to business in the evenings than enjoying themselves in taverns. But a Corporation has a character to uphold, and should be above suspicion. Are not doubts likely to arise when officials can pass judgment on work which they executed when posing as ordinary individuals? It was also reported that one of the City architect's assistants "acted professionally for outside clients" after his office hours. The assistant considered that the standing order did not apply to the case of an official availing himself of his professional training and working for private clients after office hours. The committee, however, were of opinion that if this reading of the standing order were to hold good, it would tend to lessen the independence of the official between the Corporation and the public, and it was with a view to maintaining that independence that the standing order was framed. There was no toleration allowed in the case of the architect, and he will have to respect the standing order.

THE twenty-fourth course of lectures and demonstrations for sanitary officers will be commenced on Monday, the 27th inst., when Dr. LOUIS PARKES will give an introductory lecture on "The Outcome of Sanitation." The following lectures will follow during the term:—"Sanitary Law, English, Scotch and Irish; General Enactments Public Health Act, 1875; Model Bye-laws, &c.," by Mr. HERBERT MANLEY, M.A., Medical Officer of Health, West Bromwich; "The Law Relating to the Supervision of Food Supply," and "Sanitary Laws and Regulations Governing the Metropolis," by Mr. A. WYNTER BLYTH, Medical Officer of Health, St. Marylebone; "Objects and Methods of Inspection, Nuisances, &c.," by Mr. J. F. J. SYKES, Medical Officer of Health, St. Pancras; "Factories, Workshops and Offensive Trades," by Professor A. BOSTOCK HILL, Medical Officer of Health, Sutton-Coldfield, &c.; "Water Supply, Drinking Water, Pollution of Water," by Professor W. H. CORFIELD, Medical Officer of Health, St. George's, Hanover Square; "Infectious Diseases and Methods of Disinfection," by Mr. HENRY R. KENWOOD, Medical Officer of Health, Stoke Newington; "Diseases of Animals in relation to Meat Supply, Characteristics of Vegetables, Fish, &c., unfit for Food," by Mr. ALFRED HILL, Medical Officer of Health, Birmingham; "Principles of calculating Areas, Cubic Space, &c., Interpretation of Plans and Sections to Scale," by Mr. J. OSBORNE SMITH, F.R.I.B.A.; "Ventilation, Warming and Lighting," by Mr. JOSEPH PRIESTLEY, Medical Officer of Health,

Lambeth; "Sanitary Building Construction," by Professor T. ROGER SMITH; "Details of Plumbers' Work," by Mr. J. WRIGHT CLARKE; "Sanitary Appliances," by Mr. GEORGE REID, Medical Officer of Health, Staffordshire County Council; "House Drainage," by Mr. W. C. TYNDALE, M.Inst.C.E.; "Scavenging, Disposal of House Refuse," by Mr. CHARLES MASON, Surveyor, Vestry of St. Martin's-in-the-Fields; "Sewerage and Sewage Disposal," by Professor HENRY ROBINSON, M.Inst.C.E.

A MEETING of the Flintshire County Council was held on Wednesday, when a communication was read from the clerk to the St. Asaph Diocesan Registry on behalf of the dean and chapter. It stated that, by reason of the operations of the road authorities in tiling the footpath at St. Asaph, the foundation of the cathedral wall had been exposed. The committee were asked to order that the portion so exposed should be pointed with cement. The surveyor to the Council said that he had seen the agent to the dean and chapter, and that gentleman considered that the dean and chapter were liable, but the caputular body, on the other hand, thought that the Council were liable; so nothing had been done. In the dispute over liability, which might occupy an endless period, we hope it will not be forgotten that there is a risk to the building. Let the safety of the cathedral be secured by the Council as the operators in the transaction, and then let steps be taken to recover the outlay.

THE first light railway in England is now open. It connects Chichester with Selsey. The gauge is 4 feet 3½ inches, which enables a junction to be formed between it and the London, Brighton and South Coast Railway. There are four stations on the line, but we hope they are only temporary and that the traffic will allow of the erection of more fitting examples. The canal is crossed by a draw-bridge. At present the line terminates at a point about 200 yards distant from Selsey Church, but it will be advantageous to extend it before next summer for about half a mile in order to bring visitors nearer the sea. One of the objects of the tramway is to facilitate communication with Selsey, which is likely to become a popular watering place. The success of the experiment depends in a great measure on the locomotives. The company were wise when they gave the commission for the two required to Messrs. PECKETT & SONS, Atlas Locomotive Works, Bristol. The "Chichester" and the "Selsey" were specially constructed by this firm for mixed traffic, such as they are likely to have on this line. The "Chichester" is a six-wheeled engine (four wheels coupled), and the "Selsey" four wheels coupled, with a two-wheel "pony truck" at each end, so that the weight is distributed. In consequence a light rail is able to be used and economy is secured. The working of the line will be watched with much interest, and it is not unlikely that from other districts orders for similar locomotives will arrive.

It is proposed to purchase a hall at Pitlessie as a memorial of Sir DAVID WILKIE, R.A., the Scottish painter. A church which was altered to a hall, with a cottage and garden for a caretaker, being available, the property was purchased. The committee, in explaining their action to the subscribers, who anticipated that the memorial would take the form of a statue of the artist, say:—"The amount subscribed is not sufficient for the erection of a proper statue of the artist, and the committee are of opinion that any structure, such as an ornamental fountain, would be quite out of place at Pitlessie. After being examined by an expert the hall purchased is found to be in fairly good repair, and will cost little for any alterations necessary. It has all the fittings required as a place of entertainment for Pitlessie district. The hall will of course bear the name of the great artist, and a memorial tablet—plain or elaborate, according to the funds at command—will be placed in a conspicuous position in the front. It is also proposed that a small room connected with the hall should be set apart for the purpose of preserving any picture or other article connected with WILKIE which may be either gifted or bought. The memorial is not one which is worthy of so great an artist; but WILKIE would probably consider that a painter like himself would have many an opportunity to find subjects in the hall.

VARIATION OF ELECTRICITY SUPPLY METERS.

A PAPER on this subject was read before the British Association at Toronto on August 24. Mr. RICKS's paper contains much information which confirms our remarks two weeks back on the errors in supply meters, especially those due to variations in temperature.

It has been known for some years by engineers and electricians who have had to do with supply meters in their experimental stage that the most serious error which, as a rule, has been uncorrected, is that due to temperature variations. Many inventors have admitted their inability to correct this, others have left the error uncorrected, trusting to the fact that tests of the effect of variations in temperature are seldom if ever made by purchasers. We called attention to the fact that the test for temperature error was omitted, and mentioned that it was often greater than many of the other errors.

The object of the tests described in the paper under review was "To afford a means of studying the behaviour of direct current electricity supply meters with regard to variations in the accuracy of their indications under varying conditions of temperature, current and pressure."

"The first of these tests was carried out at three different temperatures, namely, about 2 deg. C., 18 deg. C. and 40 deg. C., which may be fairly taken as the extreme and mean ordinary working temperatures."

The meters tested were of the THOMSON, SCHUCKERT, FERRANTI, PERRY and the CHAMBERLAIN and HOOKHAM types, these being taken to fairly represent the usual ones met with in this country.

The apparatus for keeping the temperature constant and for regulating and measuring the currents employed was described fully, but can have technical interest only.

Mr. RICKS spoke about the method by which he studied the variations of the speed of meters, and as it is the one which has been found reliable and convenient by many, and in fact nearly all, experimenters on meters, it may be of interest to give an abstract of what he said:—

"The accuracy of supply meters is most conveniently studied by experimentally ascertaining to what extent the constant or multiplier differs from its declared value under different conditions. By putting the result as a curve of variation one obtains a clear indication of the behaviour of the meter as regards the accuracy of its readings. The multiplier referred to is the number by which the amount indicated by the meter must be multiplied to give the true value in watt hours or ampere hours as the case may be. Hence the constant or multiplier may be defined as the ratio of the true value to the indicated value. To obtain the actual value of this constant experimentally much time and labour can be saved by observing the revolutions of the armature instead of taking the dial readings in the ordinary way, for since they are connected simply by multiplying mechanism their motions are proportional. All that is necessary is to determine once and for all the number of revolutions of the armature which corresponds to the registration of one unit on the dial."

In testing, therefore, there are in general three quantities to be measured, viz. current, potential difference and speed.

"The speed of the armature was observed by noting, by means of a stop watch, the time taken for a convenient number of counted revolutions. The intervals of time measured was never taken less than 5 minutes." This being the case, there is no doubt that the error of observation in time and revolutions would be very small.

Coming to the actual results, each meter is clearly described. As these descriptions are unusually clear and do not to any great extent depend upon diagrams, we can with advantage give extracts from them.

The ELIHU THOMSON meter "may be regarded as a form of electro-dynamometer so arranged that, instead of merely indicating power, it integrates it with regard to time, and so measures the amount of energy that has passed. The general principle of all such meters is that a small fraction of the power to be integrated is employed to produce motion in an armature. If the velocity of the armature can be made exactly proportional to the whole power, then the number of revolutions of the armature in any time is a correct measure of the total energy that has passed."

There are "two coils of thick conductor which carry the main current. The field thus produced is proportional in strength to the current, and in it is placed the armature, which is drum-wound, without any iron in its core. Its windings form part of the high-resistance pressure circuit. Since there is no iron in the magnetic circuit, the driving torque thus produced is proportional to the current and pressure. . . . Fixed to the spindle at its lower end there is a large copper disc, rotating in a non-uniform but constant magnetic field, supplied by two or three permanent magnets. The reaction between the *FOUCAULT* (or eddy) currents induced in the disc and the magnetic field producing them gives the required retarding torque proportional in magnitude to the velocity." The meter neglecting friction runs at a speed proportional to the power passing, and the number of revolutions to the amount of energy that has passed. The friction which is not quite compensated for makes the starting current, *i.e.* the current which may pass before the meter moves, about 14 ampere in a 10 ampere meter, or about 1.4 per cent. of the maximum. This makes the "constant" infinity at all currents below 14 ampere. "The constant then falls very rapidly as the current increases, not, however, reaching its normal value (that is, the correct one) till the current has risen to about 40 per cent. of its maximum value, after which it remains remarkably constant till within 10 per cent. of the maximum, when it begins to rise slightly (*i.e.* the meter runs slower again than it should do). If the solid friction is entirely compensated for, the amount of continually absorbed energy in the pressure coil would be increased, and the meter would be liable to start when no current is being used on the circuit, should the pressure increase slightly."

The effect of temperature change is shown by curves. Except for low currents, these curves (connecting constant and temperature) are practically straight lines. The constant decreases proportionally to the rise of temperature (that is, the meter runs faster at the higher temperatures). The constant in the meter tested varied from 1.06 at 0 deg. C. to .96 at 30 deg. C., or 10 per cent. variation for a range of 30 deg. C. This is a very serious error, and it must be reduced if the meter is to have any pretensions to accuracy. It is of no use to make a meter accurate within, say, 1½ per cent. for currents from one-tenth to full load, when a slight increase of temperature will make an error of 5 per cent.

The SCHUCKERT meter is next mentioned, but as it is very similar to the THOMSON there is no need to describe it fully. The meter reads more accurately than the THOMSON at the low currents, and the temperature error is less.

The FERRANTI meter is one of an entirely different character. "The action of this meter is dependent on the principle that when a current is passed radially through a fluid which is in a perpendicular magnetic field, the fluid tends to move in a direction at right angles to the directions of both the current and the field."

A disc-shaped insulated chamber contains the mercury; it is made of vulcanised fibre, and is fixed to one pole of an electromagnet, the other pole being just above it. The electromagnet is energised by the main current in a coil, and is designed so that the magnetic field is very nearly proportional to the main current. The current enters the mercury at the central part, and flowing radially outwards enters the coil by means of a metal rim, and then leaves the meter.

"The chief retarding force is that due to fluid friction of the mercury against the sides of its chamber, which are stamped with radial grooves to increase the effect and make it proportional to the *square of the speed* over as large a range as possible." The force tending to move the mercury is proportional to the current and the field, the field being approximately proportional to the current; the force is thus proportional to the current multiplied by the current—that is, the *square of the current*. Thus the speed of the mercury would be proportional to the current. "The motion of the mercury is transmitted to a very delicately-made counting mechanism by means of a vane immersed in it, and having a small vertical spindle which gears into the counting mechanism. Very pure mercury is used, and the spindle is of very small section at the part where it breaks the surface, so that skin-friction is not very great."

"The counting mechanism introduces a small amount of solid friction which is practically constant, and is compensated for by using mild steel for the magnet core, which then has a small amount of permanent residual magnetism."

The author says that the meter is made up in an extremely compact form, and has the great advantage of simplicity of construction. "It possesses, however, the disadvantages attendant upon comparatively small driving and brake forces, necessitating the employment of an exceedingly light and frictionless counting mechanism, which, owing to its very delicate construction, must require very careful handling." Pure mercury is also essential. We entirely agree with the author on these points, and would add another disadvantage, viz. the high speed of the parts.

This meter is extremely curious in its results, which differ from those obtained in any other meter.

"In the first place, the constant at low currents was found to have a low value." Thus the meter runs fast at low loads. This is no doubt due to the fact that fluid friction is proportional to the speed, not to the square of the speed at slow speeds. "Then it was noticed that for any given value of the current the constant varied according to whether the current had risen or fallen to that value." The author makes a great point of this lag of magnetism behind the current.

It has, of course, been known to careful experimenters on this meter for years. It is the effect found in all instruments in which there is iron, the magnetism of which is being varied. It is no doubt large in this instrument, because of the use of a mild steel which retains some permanent magnetism, and therefore has large hysteresis. It is, in fact, the price paid for the low-starting current. The error is no doubt a serious one, and it is more serious at light loads, it being of an amount approaching 10 per cent. at quarter load. The remedy is to get softer iron for the magnet, and either put up with a little higher starting current or find some other way of decreasing the effect of solid friction of the moving parts than by having residual magnetism. We leave this problem to Mr. FERRANTI with confidence, and feel sure that his ingenuity will overcome the difficulty.

The constant of the meter hardly alters with temperature, but the meter runs rather slower at a higher temperature.

The next meter described is the PERRY. This again is a meter which works under conditions differing from any type yet mentioned.

The meter consists of a copper cup, which rotates between concentric poles of a powerful permanent magnet, the pole pieces being cut away to form discontinuities in the magnetic field. The axis of rotation of the copper cup is vertical. The spaces cut away in the pole pieces are filled up to preserve the cylindrical form of the annular space in which the cup revolves. This space is filled up with mercury, the inverted cup being wholly immersed in the mercury, except where the spindle passes through the skin of the mercury. The inner surfaces of the pole pieces and the copper cup are painted with an enamel, except at the bottom, which in the case of the copper cup is nickel-plated, to preserve it from the action of the mercury. At the top of the spindle is a pivot in a small mercury cup, and the whole is kept central by a guide-pin fixed on the top of the inner pole piece, working in a guide inside the bottom part of the spindle. Current enters this armature through the upper mercury cup, and leaves it at the bottom rim, the current going through the mercury to the iron pole piece, which is left unpainted at the bottom, and from there to the lamps. "Solid friction is not compensated for in this meter, but is made very small compared with the other forces, by so adjusting the weight of the copper cylinder that it just floats in the mercury. There is very little skin-friction, because of the very small diameter of the spindle at the part where it passes out of the mercury."

The driving torque on the meter is proportional to the current only, the field being constant; the retarding forces are (1) solid friction, (2) fluid friction, (3) FOUCAULT current friction. Solid friction is made very low owing to the slow speed of the meter; fluid friction is reduced as much as possible, and at the slow speeds is proportional to the speed; and the FOUCAULT current is extremely large, swamping the others, and is proportional to the speed. Thus the speed of the meter is proportional to the current. The

temperature error in this meter is high. The resistance of the copper cup increases with an increase in temperature, and the effect of FOUCAULT currents decreases, the viscosity of the mercury decreases, and for these reasons the speed increases. The magnetic field decreases with increase in temperature, thus the torque or driving force decreases, therefore neutralising to some extent the tendency to run faster, but the FOUCAULT currents, being proportional to the square of the field, are decreased to a much greater extent, thus allowing the meter to run faster still. This latter, and the increase in the resistance of the copper cup, are by far the most important causes of increase in speed.

Mr. RICKS is obviously wrong when he says, "The weakening of the permanent magnets with rise of temperature would scarcely have any effect on the constant, because it would, except perhaps at very low currents, alter the driving and retarding forces in almost the same ratio." This is incompatible with the fact that the driving force is proportional to the field, and the retarding force proportional to the square of the field.

The inaccuracies in this meter due to temperature are rather large, viz. for 30 deg. C. rise in temperature the meter runs 12 per cent. faster, and this is serious. The great advantages of this meter are (1) mechanical strength; it is an engineer's rather than an instrument maker's meter. (2) The speed is low, and the energy absorbed is extremely low—only 1.32 watts at maximum load.

It is, in fact, a very good meter where the temperature does not vary much.

In the CHAMBERLAIN and HOOKHAM meter, which is very similar to the above in principle, the driving force and the brake are separated. "In this meter two metal discs are employed, rotating upon a vertical spindle in a permanent magnetic field, the direction of which is parallel to the spindle. The current in passing radially through one of the discs gives rise to a driving torque, which, since the field is constant, is proportional to itself. A retarding torque proportional to the speed is supplied by FOUCAULT currents in the other disc."

The armature field is increased by means of some series turns as the current increases, thus keeping the speed up to the normal through a greater range.

The radial grooves on the pole pieces in the brake are arranged so that the iron in them is saturated; consequently, a considerable decrease in the total field due to temperature does not affect the brake. For this reason the increase in speed due to temperature increasing is only about one-half that in the PERRY meter. The starting current is rather less than in the PERRY, the power absorbed seven times as much. The meter is not so strong mechanically.

It may be of interest to give some of the more important figures obtained in tabular form:—

Meter.	Max. Amps.	Volts.	Power Wasted at Max. Current, Watts.	Starting Current, per cent. of Max.	Temperature Co-efficient.
Thomson	10	100	12.8	1.4	-.32
Schuckert	15	110	14.67	1.93	-.13
Ferranti	25	—	8.19	.8	+.07
Perry	20	—	1.32	1.25	-.47
Chamberlain & Hookham	25	—	9.8	.8	-.22

In conclusion, we may say that the paper will serve a very useful purpose by drawing public attention to the errors in meters, which have been unknown to any but those who have very carefully tested them, and who have usually had good reasons to conceal the errors. In most cases the investigator is the inventor or his assistant.]

CANTERBURY SCHOOL.

THE following interesting paper on "The Origin of Canterbury School" appeared in the *Times* on Tuesday last:—

We have been hearing a great deal lately about Canterbury as the first seat of English Christianity; it has not hitherto been recognised as the first seat of English education. Yet there is every reason to think that it is, and that its public school may trace its origin to King Ethelbert of Kent.

The King's School, Canterbury, though it may legally date only from Henry VIII., is, in fact, a re-foundation of what existed long before him. There were at Canterbury in, or in connection with, the Church and the Archbishop, three educational establishments before the dissolution of monasteries. There was the Monastic School in the Cloister, the School of

the Novices, under one of the senior monks. It can be inferred from a few (very few) scattered notices to have existed from before 1067 to 1494, and, if it fell into desuetude then, to have been at least for a time revived in 1511. There was the Almonry School in the Almonry, on the very site of part of the King's School buildings, probably not existing before 1320, but appearing in a considerable number of documents from that date to 1450. The school of the monks was for novices only, for boys brought up in the monastery intended for monks from their tenderest years, or for those who came in at a later age to be admitted as monks. This school could never have numbered more than a score at a time, and for the most part did not exceed ten or a dozen at the outside. The Almonry School was a charity school, under a cleric, not a monk, for a few poor boys intended to serve as choir boys in the Almonry Chapel. Like the choristers of Winchester College, they waited upon the members of the foundation, though at Canterbury they only waited on the monks when the latter were in the infirmary. The number of this school did not probably exceed thirteen.

Besides these two schools, there was the school of the City of Canterbury, the school of the Archbishop, which, if Canterbury Cathedral had been held, not by monks, but by ordinary canons, would have been called the Cathedral School. It was kept by a cleric or a layman, appointed by the Archbishop, not by a monk. It was outside the precinct of the monastery, in the parish of St. Elphege, a "peculiar" of the Archbishop's. In the fourteenth century it was apparently in the church itself, but in the fifteenth in a house in the parish. It performed precisely the same office as the King's School now, serving as the public school of Canterbury and the neighbourhood, and for all who chose to come. This and not any school of monks or the dependants of monks, of a few novices or a few charity boys, was the true ancestor of the King's School. But, as on the foundation of the King's School nine of the novices were drafted into it as scholars, the King's School may claim also to represent the Monastic School; and as it inherited, through a grant from Cardinal Pole, the buildings of the Almonry, and provision was made for the boarding of its fifty poor scholars in the cathedral precincts, it may also claim to represent the Almonry School.

The Novices' School and the Archbishop's School may both claim a very high antiquity. It is just possible that they represented an eleventh-century bifurcation of one original school. For the Novices' School some very minute directions are given by Lanfranc in his "Benedictine Constitutions," which, though treated and no doubt intended as general rules for the whole Order of Benedictine monks in England, were, in fact, addressed to the Prior of Canterbury in particular. Eadmer, precentor of the monastery, who in the eleventh century wrote an elaborate description of the Saxon church as it was before it was burnt down in 1067, tells us that he himself was a boy in the school at the time of its rebuilding by Lanfranc, and informs us precisely where the monastic school was held before the rebuilding, namely, in the north tower of the church, the south tower being used as the Supreme Court of Appeal for the (Kentish) kingdom.

The record evidence of the "School of the City of Canterbury" hitherto come to light dates only from 1290. From that time to 1472 it is fairly copious. There are over thirty documents, and references to fourteen different masters between those dates. As ushers, monitors and vice-monitors are mentioned it must have been a school of considerable numbers. It enjoyed a monopoly of grammar school teaching in the city. In 1322 a rival school in another "peculiar" of the Archbishop's, St. Martin's parish, was not allowed to derogate from that monopoly to the extent of more than thirteen grammar scholars, though it might have as many as it could get in elementary subjects. No other grammar school was allowed at all. That this Canterbury School continued right up to the dissolution cannot be doubted (though in the later years the registers are silent), under prelates like Cardinal Morton and Archbishop Warham, scholar of Winchester, Fellow of New College, who made even the lazy monks learn grammar. It is said that Twyne, the first master of the King's School, had been master of the school. Though not proven by documents this is highly probable, as he, a Hampshire man, a stranger, was admitted a freeman of the city in 1538, two years before the reconstitution of the Cathedral School.

As to its upward limit of antiquity no bounds can be set. In a case in the Ecclesiastical Court of Canterbury in 1312 evidence was given of the custom of the school "for forty years and upwards," carrying us up to 1272 at least. Somner, who dedicated his well-known "History of Canterbury" to Archbishop Laud in 1640, cites a document, not now forthcoming, in which the schoolmaster appears in 1259.

Unfortunately there is small hope of more records being discovered about it. The archiepiscopal records from Lanfranc's time downwards were carried off to Rome by Archbishop Kilwardby, who resigned the see on becoming a cardinal in 1279. His successor vainly tried to recover them, and they

have not been seen since. The earlier cathedral records were, as we learn from a contemporary historian, destroyed in the fire of 1067.

Yet it cannot be doubted that the school existed from before the Norman Conquest. As the constitution of the Chapter before that date, whether it was inhabited by secular canons alone or by monks mixed with seculars, is wrapped in controversy, the exact constitution of the school must remain in doubt. What is certain is that the church was not served by monks alone, and that the school, therefore, was not simply, if at all, a monastic school. That a school existed at Canterbury before the days of Archbishop Theodore, the reputed founder, and, while certainly not diminished in efficiency by him, was equally certainly not founded by him, is beyond controversy.

The proof of this lies in a small compass. For the history of England and the English Church, and therefore of English education, from the advent of Augustine to the first quarter of the eighth century, there is only one original authority, Bede. William of Malmesbury, Florence of Worcester, the eleventh and twelfth-century biographers of saints, even the Saxon Chronicle itself, are only copyists and commentators, embroiderers and embellishers of that first great historian of the English race. Theodore, a Greek ex-monk, made archbishop (in place of an Englishman who died of the plague at Rome, with all his company), "a man instructed both in secular and divine literature, Greek and Latin," at the age of sixty-six, arrived at Canterbury on May 27, 669. He was quickly followed by Hadrian, an African, sent by the Pope to accompany him and look after his orthodoxy. Hadrian was a monk from near Naples, "diligently imbued with the sacred writings, instructed alike in monastic and ecclesiastical learning"—the distinction is notable—"and of the greatest skill equally in the Greek and Latin tongues." He was made abbot of St. Peter's and St. Paul's, afterwards St. Augustine's Abbey. Now comes the crucial passage as to Theodore:—

"Soon (mox) he journeyed through the whole island wherever the English races were settled, for he was gladly received and listened to by all, and spread abroad the right rule of life, the canonical mode of celebrating Easter, Hadrian accompanying him and working with him in everything. And he was the first archbishop whom the whole English Church consented to obey. . . . And because both—*i.e.* Theodore and Hadrian—were, as we have already said, abundantly learned both in sacred and profane literature, assembling a crowd of disciples, streams of saving knowledge daily flowed from them to irrigate their hearts; so that, with the volumes of the sacred writings, they handed on to their hearers instruction both in the art of metre and astronomy and ecclesiastical arithmetic. The proof is that even to this day there survive some of their pupils, who know Latin and Greek equally with their own tongue in which they were born."

Bede then descants on the happiness of those times in which powerful Christian kings were a terror to all barbarous tribes, and every one set his heart on the newly revealed joys of heaven, "and whoever wanted to be instructed in holy lessons had masters at hand to teach them." Not only did these masters teach languages, but also "the tones of song in church, which hitherto they had known only in Kent." And so, goes on Bede, Theodore, "inspecting everything, ordained bishops in fit places, and with their help put right what he found needing correction."

It is quite obvious from the wording and the context of the passage that Bede was not speaking of Canterbury at all. The point he was bringing out was that Theodore was the first "Primate of all England." He was the first to unite in one Church, under one head, the separate Churches of the different kingdoms into which the English were divided, "evangelised" as they had been from quite different sources—by Romans in Kent, by Scots-Irish in Northumbria, by Burgundians in East Anglia, by Franks in Wessex. To effect this he traversed the whole country, teaching and organising as he went. If Bede meant to credit Theodore with founding any schools, apart from acting as an itinerant Society for Promoting Christian Knowledge, it was not with a school at Canterbury, but with schools attached to bishoprics in Mercia, East Anglia, or Northumbria, and with introducing Greek in addition to the usual Latin. It is worth noting, too, that the special subjects of instruction by Theodore were, first, the "art of metre" or prosody, no doubt with a view to preventing those false quantities in the Psalms and lessons, to cure which Archbishop Warham long afterwards ordered the ignorant monks of Canterbury Cathedral to keep a grammar schoolmaster. Next came astronomy and ecclesiastical arithmetic, the main object of which was to calculate the calendar properly for the movable feasts, especially Easter, which the Celtic Church, adhering to the ancient method, celebrated sometimes a week before the Roman Church.

Neither astronomy nor ecclesiastical arithmetic were subjects of instruction in grammar schools for boys. It is impossible, then, upon any reasonable construction of or inference

from this passage to attribute the founding of any school to Theodore, least of all the school at Canterbury.

The other passages in Bede in which Theodore is mentioned in connection with any educational work are only three. The first occurs *à propos* of the death of Abbot Hadrian in 710. "Of his learning," he says, "and that of Theodore, amongst other evidence is this, that Albinus, his pupil, who succeeded him in the rule of the monastery, was so well taught in the study of literature that he knew the Greek tongue to no small extent, and Latin not less than that of the English, which was his native tongue." Again, of Toby, Bishop of Rochester, who died 726, he says, "a most learned man. For he was a pupil of Archbishop Theodore of blessed memory and Abbot Hadrian; whence, as has been said, together with a knowledge of literature as well ecclesiastical as general, he learnt Greek with Latin, so that they were as well known and familiar to him as the speech of his birth."

Lastly, in his preface to the whole work, Bede says that his chief authority for all that related to Augustine and Pope Gregory and his pupils was Albinus, who had collected all the materials documentary and traditional in "the province of the Kentish men." This very reverend abbot "was the most learned man of his time in everything, having been educated in the church of the Kentish men by those venerable and most learned men, Archbishop Theodore of blessed memory and Abbot Hadrian."

This is absolutely the only passage in which Canterbury is mentioned in connection with Theodore's educational work. It may be taken as going to show (what is, of course, beyond question) that Theodore taught at Canterbury as well as elsewhere. But it is one thing to teach, another thing to found a school.

We are not, however, left to negative evidence, or conclusions drawn from silence. Bede gives us a positive statement, which absolutely disposes of any suggestion of Theodore as founder. Giving an account of the Christianising of East Anglia under King Sigebert, he tells how "when he returned home and became king, wishing to imitate those things which he had seen well done in Gaul, he founded a school in which boys should be taught grammar (*litteris*), Bishop Felix, whom he had received from Kent, helping him and giving him ushers and masters (*paedagogos et magistros*), after the fashion of the Kentish folk." But instead of Sigebert coming after Theodore, as Somner in his history assumes, and Theodore's school being a pattern to him, Sigebert reigned in 631 and died not later than 644, or close on forty years before Theodore ever set foot in this country. To Bede it was so obvious that there were grammar schools for boys already fixed and developed in Kent in 631, that it was to him a matter of course that Kent was able to send forth masters to start schools in other places. For this purpose Kent, of course, means—or at least means before all places—Canterbury. But 631 is itself within forty years of the advent of Augustine. Surely, then, the casual notice of schools in Kent as things of course in 631, the absence of any mention of the foundation of a school at Canterbury by anyone else, the implied assumption that a school is a natural appanage of a bishop, justify the conclusion that, if and so far as the Christianising of Kent and the foundation of the Cathedral Church at Canterbury are rightly attributed to Augustine (and of that there can be no doubt), then and so far must the foundation of the Cathedral School at Canterbury equally be attributed to that "Apostle of the English."

But it is said by Somner and the historical sheep that follow him, that Canterbury was "so often wasted by Danes" that Theodore's school perished. This often wasting of the Danes is an historical delusion, due simply to not regarding the authorities. Its baselessness was shown by Professor Willis half a century ago when he wrote his famous architectural history of Canterbury Cathedral Church. The cathedral was supposed to have been burnt by the Danes in 1011, when Archbishop "Saint" Elphege was captured, carried off, and afterwards killed. But Eadmer, already quoted—an Englishman, and in the monastery not fifty years after the event of which he gives a circumstantial account—asserts point-blank that the cathedral, though "attacked" by fire for the sake of driving the archbishop out, was not burnt, but remained to his day.

Moreover, within ten years of the "martyrdom" of Elphege, Canute the Dane, now a Christian king, accompanied by the English Archbishop Egelnth, visited Canterbury in state and "translated" thither the remains of the martyr.

But this is the only time mentioned by the ancient historians at which Canterbury is specifically alleged to have been destroyed by the Danes, and the earliest and most trustworthy shows that it was not destroyed. The succession of the archbishops was not interrupted. Why then should the school, the grammar school, one of the chief objects of episcopal care, have been interrupted either?

In spite of Danish and Norman conquests, in spite of changes of the Chapter of Canterbury from secular clergy to monks and back to secular clergy, the regular succession of

archbishops has gone on without break from Augustine to Dr. Temple. It is no mere guess, but a well-grounded inference, that the School of Canterbury, which was under the special care and patronage of the archbishops till the reign of Henry VIII., and since then of the Chapter of secular canons, has gone on uninterruptedly too. It may claim continuity from the era of Ethelbert to the era of Victoria.

THE CASTLE OF PULVERBATCH.*

WE are standing at the present moment on the site of one of those manorial residences which are scattered along the western border of Shropshire in considerable frequency, to which the name castle has been applied with propriety, serving to distinguish them from moated manor-houses. They belong to a group of inferior importance to the large Norman and Mediæval castles such as Shrewsbury, Ludlow and Bridgnorth. We may class this one with Wooltaston, Brocards, Minton, Bishop's Moat, and such like. It stands on the edge of a ravine, the steep slope protecting it effectually on the south side, while on the other sides it was defended by artificial works, which even now, after centuries of weathering, are well marked. On the west is the conical mound on which the keep stood. East of this is an oval enclosure forming a court or bailey, divided from the mound by a deep ditch. Another ditch encloses both mound and court where not otherwise protected by a steep declivity. These works indicate the area occupied by the Saxon castle. The keep may have been originally a lofty tower constructed of solid blocks of timber bound together by cross ties, two or three storeys high, affording accommodation for the lord and his family. On the top of this tower would be in times of danger a watchman and a beacon to warn the neighbourhood of the approach of enemies.

Along the brow of the escarpment, enclosing keep and court, would be a strong palisade of timber, outside of which was the ditch—in this case not supplied with water, but having such obstructions to an enemy placed in it as the ingenuity of the defenders could devise.

Now I would especially call your attention to another large court on the north side, which I regard as the Norman addition, encircling which are also a wall of earth and a ditch. When this was made it is not improbable that stone replaced the wooden defences which I have mentioned. Eyton supposes that the whole of these earthworks is the site of a Norman castle founded by Roger Venator; but the southern portion accords so well in size and form with those now recognised as of Saxon date that it is highly probable its foundation was prior to the Norman Conquest, though doubtless enlarged and improved upon by its Norman owner, as were Hodnet and Shrewsbury castles. It is a fallacy to suppose that Saxon landowners could have dispensed with such fortified structures as these. Indeed it was the possession of such places that gave William the Conqueror so much trouble long after the battle of Senlac had put him on the English throne. Freeman, in his "Norman Conquest," says that "none knew better than the Conqueror himself how far the land still was from being conquered. William was king, but he knew well that in the greater part of his kingdom his kingship as yet hardly existed but in name." And again, he says, "The true way of looking at those important stages of the Conquest which followed William's coronation seems to be this. The opposition which William met with was in truth the stubborn resistance of a land striving to guard the last fragments of its freedom against the assaults of a foreign invader who was winning the land bit by bit." Now we cannot suppose that this state of things could have been thus prolonged unless the Saxon owners of the land were prepared to impede the conquerors by fortified positions, such as the one before us, numerous distributed throughout the country. It was this capability of obstruction to his government that necessitated the transfer of land as speedily as possible from the intractable Saxon possessors to the creatures of the Conqueror, by slow but certain steps. Twenty years after the battle of Senlac, when Domesday was compiled, nearly every Saxon in Shropshire was disinherited. Among these were two brothers Hunnit and Uluiet who possessed this castle and manor of Pulverbatch. William conferred nearly the whole of Shropshire on Roger de Montgomery, and he in turn conveyed Pulverbatch to Roger the Hunter, or, as the Norman scribes were pleased to call him, Roger Venator. One of the consequences of this change of ownership was the astonishing decrease in value of the manor, falling five-sixths in its rental.

Roger Venator held other property in Shropshire, but he made Pulverbatch the head of his barony, and on this very spot held his manorial court, and exercised those powers which made the Norman barons so hateful to the English. Those powers were comprehended in holding pleas of the Crown,

* A paper read by Mr. W. Phillips at an excursion of the Caradoc and Severn Field Club, and published in the *Shrewsbury Chronicle*.

having free-warren, a market, a fair and ways. The full meaning of these terms it would occupy too much time to explain. It was almost absolute power, for although a jury was impanelled in the court, it was not likely to be other than subservient to the lord.

Roger Venator, says Eyton, was a younger brother to Norman Venator, the ancestor of the Pitchfords. The two brothers attested Earl Roger de Montgomery's foundation charter of Quatford Church, probably in the very year when Domesday was compiled. The descendants of Roger Venator were ancestors through females of several Shropshire families of distinction, among which may be mentioned the Constantines of Eaton Constantine and Oldbury, the Uptons of Waters Upton, the Stapletons of Stapleton and Wistanstow. His family in the male line continued here as late as the reign of Henry II., the last being Reginald de Pulverbatch, who left Emma, his daughter, sole heir. Certain documents are still extant in which Emma grants to Henry, son of Eyric de Wesseleg, half a virgate of land in Wesseleg, and the whole of a certain moor called Humbermor. She also grants easements in the wood of Pulverbatch, and pannage throughout her whole fee of Pulverbatch, as well as Huggelith, the hill which stands within sight of us at this moment. The heir of Emma was John de Kilpec, a member of a distinguished family, some of which were keepers of the king's forests of Herefordshire.

Without entering more minutely into the succession to this manor, I may say that after the de Kilpecs had held it for several generations, in 1295 Pulverbatch came into the possession of Ralph de Botiler, and continued in the male line of his family till the reign of Queen Elizabeth.

It was during the minority of one of the Kilpecs, John de Kilpec, that King John in 1205 informed the Sheriff of Staffordshire that he had given the custody of John de Kilpec's land to William de Cantilupe. On February 8 following, the king informs the Sheriff of Shropshire that he has entrusted his (the king's) castle of Pulverbatch to William de Cantilupe. The sheriff is to give it up with all arms and chattels found therein. This is the first mention of the castle I have met with, though of its continued existence and occupation there is no doubt. By an escheat roll of the sixth year of Henry VI., we learn that there was a free chapel belonging to the castle in the patronage of Edward de Botiler.

I have supposed this to have been of Saxon foundation, but how far enlarged and strengthened by masonry we know not. One fragment of wrought stone built into a wall on the right-hand side of the narrow road leading down to the highway is the only fragment to be seen. This was pointed out some years ago by the late William Hill, the well-known carver, who formerly resided near here. This stone you should have seen but I could not find it, and it is all that remains to convince us that there once stood on this now desolate site a stone structure of importance dominating the manor. It may be that carefully-conducted excavations may bring to light further remains of masonry to indicate the period of its construction. I regret that we have no information as to when it became dismantled. It took no part in the civil war of Charles I., nor is there any mention of it, as far as I know, in the reign of Elizabeth, which leads to the supposition that it was abandoned as a ruin at an early date.

If I have not already wearied you, I should like to say a word or two on the derivation of the name Pulverbatch, which, although having received the attention of very able men, appears to me far from being settled satisfactorily. I will read you what Eyton has written on the subject in his splendid work "The Antiquities of Shropshire":—"As the modern *Wel-batch* figures in Domesday as *Huelbec*, so *Pulverbatch* was spelt *Polrebec* by the Norman scribes who registered the survey. About this termination, *bec* or *batch*, there are two opinions. Mr. Blakeway cannot forget that *bec*, in the North of England, is a little brook, nor that the German form, *bach*, is found in other Teutonic dialects. In Shropshire, the situation of Beckbury and other places on or near streams suggests the same etymology. However, Mr. Blakeway acknowledges that it can hardly be said there is a brook at Pulverbatch; and I cannot find in the Saxon glossaries any word like *bec* or *bach*, significant of a stream. Mr. Hartshorne, on the other hand, asserts the existence of a Mercio-Saxon word, *bach*, signifying a bottom or valley. I cannot doubt that in Shropshire and Staffordshire names the word *batch* has the latter signification. I must join Mr. Blakeway in hazarding a somewhat bold opinion as to the etymology of the other part of the name Pulverbatch. It is clear that this district was well-known to the Romans, and I cannot but see that Roman and Saxon words are compounded in such names as Pontesbury, Pontesford and Pitchford. Why, then, should not the Latin noun, *pulvis*, *pulveris*, be accepted as the component of Pulverbatch? Mr. Blakeway says that the district in summer is literally 'a bed of dust.' It is, moreover, easy to see that a Norman scribe, well knowing, as every Domesday scribe did, the meaning of the Latin part of the word *Pulver-batch*, should write it as *Polre-bec*, for *Polre* is,

within a letter, the same as *Poldre*, and this is the old French word for dust—the original, in short, of our word powder. Lastly, one fact is known to all dwellers in the neighbourhood of Pulverbatch, viz. that in the local dialect the place is pronounced Powderbatch to this day" (vol. vi. p. 188).

Now with regard to the batch in this name, few will differ with Mr. Eyton. It is so commonly used in Shropshire for depressed hollows, such as we see from this castle mound, that the very spot confirms his contention. But with regard to the place being more dusty than other places in the district, notwithstanding the high authority of Mr. Blakeway and Mr. Eyton, I must entirely differ from them, and as a consequence humbly reject their explanation.

It will be thought presumptuous on my part to offer a new and what I venture to consider a much more probable explanation of the first member of the name, and I shall probably incur severe criticism for my temerity.

You will bear in mind that the Norman scribes wrote the name Pulverbatch *Polerebec*, just as they received it from the Saxon dwellers; and further, the name probably indicated the physical features of the place. If you take the ordnance map and trace the water-courses you will see that in this *bach* several join here to form a stream which ultimately falls into Condover brook, and may have been considered the head of the brook. Now in *Polre* we have combined two members—*Pol*, meaning head, and *re*, meaning brook or stream. The first of these we have in poll-tax, a tax levied by the poll or head. Also in pollard, a tree having its top cut off. It is said to be derived from the Danish *bol*. The second, *re*, or *rhe*, we are familiar with in the name of the Rea, which rises near Marton and enters the Severn at Shrewsbury. And again in the river Rea in the south of the county. If I am correct, therefore, we have the physical features of the place condensed into a trisyllabic word *Pol-re-bec*, meaning head of the brook-bach.

The reading of this paper was listened to with great interest in spite of wind and rain. The steep mound of the keep was then examined and the entrenched inner court. Descending thence into the road, and crossing the little brook referred to in the paper, the party walked up a narrow, steep lane, and across the open hilltop to Underhill Hall, and partook of a very welcome tea. During the progress the rain cleared off, and lovely views were obtained towards the north and east. Walking down again to Castle Pulverbatch, the carriage was rejoined, and a start made homewards at 7.30. Shrewsbury was reached about an hour later, the return route being *via* Stapleton and Bayston Hill. The evening was beautiful, and the clouds and sky tinted most exquisitely with all hues of red, green and gold by the setting sun.

BIRMINGHAM BATHS.

CORPORATIONS and other local authorities have of late years to take a share in a system of mutual improvement. When a new work is contemplated it is usual to send a deputation of members to various places where similar works were executed, and besides opportunities of inspection it is expected that a large mass of information will be supplied which can be used as a basis for the report of the visit. Birmingham, being one of the most progressive of cities and having, moreover, a regard for economical expenditure in all things, is naturally among the first places sought by committees who are in quest of knowledge. As the preparation of statistics and details for visitors is an onerous task, Mr. J. Cox, the superintendent and engineer of the baths department, has by permission of the committee prepared a book which is a comprehensive history of the public baths of Birmingham and explains their acquisition, cost and annual maintenance, with copies of the Baths and Washhouses Acts, subsequent Amendment Acts and the by-laws framed for the management, use and regulation of such establishments. It also contains statistics of the number of bathers, and receipts and expenditure on account of each department from the date of opening up to the present time, with a summary of the expenditure incurred for the provision, erection and maintenance of these and similar institutions in other large towns and cities. Detailed plans, giving the dimensions and accommodation provided at each of the baths, are included in the work, with a general map of the city. Some extra copies have been printed to satisfy the demand for information on the subject, and can be obtained at cost price (3s. 9d.) by all who have an interest in sanitary affairs. The book serves its purpose so well, we suppose the heads of other departments will follow the example of Mr. Cox and prepare similar volumes relating to other branches of municipal work in Birmingham.

The oldest of the four bathing establishments in Birmingham is in Kent Street. It was opened in 1852, but there have been many changes since that time. For instance, there was one improvement in the first-class swimming-bath, as the promenades were, in 1892, paved with Edwards's Ruabon "adamantine tiles." The most important addition was probably the Turkish

bath, which was opened in 1879. The question often arises whether baths of that sort are remunerative, and from the following statement it will be observed that in Birmingham the returns almost meet the expenditure:—"The average number of bathers in this department during the three years ending March 31, 1894, was 5,306, viz. 4,448 men at one shilling, and 858 women; and the average annual income for the same period was 271*l.* 7*s.* 6*d.*, against an average working expenditure of 235*l.* 10*s.* 6*d.*" At Kent Street there is also a laundry and wash-house. The water is obtained from a well which is 25 feet deep and 8 feet in diameter. During the summer months about 700,000 gallons are required weekly. Efforts are made to make the baths popular, and Kent Street is the rendezvous of six men's swimming clubs and one ladies' club. The children attending the schools of the city are also admitted on most reasonable terms, in some cases for a halfpenny each. Kent Street baths have cost about 23,900*l.*, and already a sum of 19,926*l.* has been repaid. The original architect was Mr. D. R. Hill.

The Woodcock Street baths were made the subject of a competition, in which Mr. Edward Holmes was successful. The style adopted was Gothic. They were opened in August 1860, and consist of swimming-baths and private baths. The Northwood Street baths, opened in 1862, were designed by Mr. William Martin, and cost 12,283*l.* Messrs. Martin & Chamberlain were the architects for the Monument Road baths, which were opened in February 1883. The cost was 20,251*l.* A Turkish bath was added in 1888, which Mr. Cox describes as follows:—"The walls of the hot rooms, as in the other departments, are cased with white enamelled bricks to a height of 5 feet 6 inches; the upper part and the arches forming the ceilings are built with white brick, the hot rooms are lighted by means of double-glazed vertical windows, with cast-iron frames, and to improve the lighting they have recently been enlarged. The floors are laid throughout with encaustic tiles, and the shampooing-room is fitted up with one marble slab, a needle and shower bath, with douche, spray, and other improved hot and cold water services. The various degrees of temperature are maintained by a system of steam radiators fixed in special vaulted chambers below the hot rooms, with suitable hot-air flues communicating thereto, and the temperature of No. 1 hot room is 150 deg., No. 2 hot room 175 deg., and 200 deg. in No. 3 room. A current of fresh air is supplied to the radiators, and after being heated passes through the hot rooms to specially constructed extraction flues provided in the main walls of the building with outlets above the roof, thus securing a constant current of fresh warm air throughout the building at all times. Eight lounges are provided in the lounge-room, and the plunge bath is 14 feet by 16 feet, with a depth of 4 feet 6 inches. This bath is approached by marble steps, screened off with suitable curtains and brass rods, &c. It is worthy of mention that this department is much used by some of the principal residents of the city, and is often recommended by medical gentlemen.

The income from the Turkish bath is 234*l.* 11*s.* 6*d.*, and the annual expenditure 236*l.* 10*s.* 6*d.*

Plans have been prepared by Mr. Cox (with the co-operation of Mr. H. Martin as architect) for baths at Small Heath and Balsall Heath. The former building when completed will correspond with the following description, and exemplify the latest improvements:—

The front and principal elevation will be in Green Lane, with a total frontage of 168 feet. It will adjoin the new branch library, opened on December 30, 1893, and will be carried out in the same style of architecture as that building, and which has already been described "as a building that will vie with any other public library in any district of the city for the beauty of its design and harmony of structure." There will be three separate entrances to the new baths from Green Lane, viz. one for first-class bathers, one for second-class bathers, and the central entrance will be used for admission to the women's first and second-class departments.

The ticket office will be placed in the centre of the building immediately behind the women's baths, and there will be separate ticket windows from this office communicating with the three entrances named. A private room will be provided for the use of the resident money-taker adjoining the ticket office, and other domestic apartments will be placed on the first floor immediately over the women's bath, and will form the central elevation of the building.

The first-class swimming-bath is placed on the south side of the establishment immediately adjoining the library buildings. This department will measure about 100 feet from front to back and about 60 feet in width. The water area will be 81 feet by 33 feet wide, and will have a depth of 4 feet at the shallow end and 6 feet 6 inches at the deep end, and will contain about 90,000 gallons of water. The promenades on the four sides of the bath will be 7 feet 6 inches wide, with 47 dressing-rooms on two sides and at one end. Each dressing-room will be about 3 feet 6 inches wide and 4 feet 3 inches back to front. In addition there will be a separate

room for the use of swimming clubs, one drying-room, a needle and shower bath, with the usual lavatory accommodation. It is also proposed to construct a public gallery on the two sides and at one end over the dressing-boxes, with separate stairs and entrance from the first-class corridor.

There are seventeen men's first-class private hot and cold water baths, divided into two sections, with a 4-feet corridor between. Each bathroom will be about 7 feet 6 inches long by 6 feet 6 inches wide. An attendant's room is placed at the junction of the two departments, to enable one person to supervise both if required during meal times or on other occasions, also to overlook the first-class entrance and the ticket-office window. Separate lavatory accommodation is provided for each of the departments.

The second-class swimming-bath is placed on the north-east side of the establishment, and will measure 97 feet from front to back and 47 feet in width. The water area will be the same as the first-class bath, viz. 81 feet by 33 feet, and will also contain about 90,000 gallons of water. The promenades will be 7 feet 6 inches wide; but there will be no dressing-rooms, as seats will be fixed against the outside walls, with wood partitions between each, 2 feet apart, and fitted with clothes-shelves above, giving accommodation for about 120 persons at one time. The men's second-class private baths are placed between the swimming-bath and the first-class department, and are seventeen in number, in two sections, with corridor between them, and they will communicate with the second-class entrance passage, with an attendant's room placed as in the case of the first-class department to enable the attendant to have full control of the two departments when necessary, and also the oversight of all persons passing up and down the corridors to the ticket-office window.

As before stated, the women's private hot and cold water baths will be placed in the front part of the establishment, with a separate entrance, and will consist of five first-class baths, with an attendant's room on one side of the entrance passage, and six second-class private baths on the opposite side, the whole communicating with one ticket window, and will be easily accessible by the money-taker, whose duty it will be to attend to these baths in the winter months in addition to the issue of tickets, &c.

The engine and boiler-house is placed in the rear of the establishment, with a gateway entrance and coal yard from Little Green Lane. The boiler-house will be about 57 feet long by 24 feet wide, and separated from the engine-house and engineer's workshop by half-glass screens, thus enabling the fireman to have complete oversight of the machinery whilst attending to his boilers, &c. A large cold water reserve tank, holding from 50,000 to 60,000 gallons of water will be placed on girders, supported on the walls of the boiler-house at a height of about 25 feet, and from this tank the whole of the water services throughout the establishment will be supplied.

It is proposed to construct the heating arrangements and the hot-water supplies upon the same principle as that recently adopted at the Kent Street, Northwood Street and Woodcock Street establishments, and which has proved eminently satisfactory, viz. by high-pressure steam circulation, with suitable reserve hot water tanks. Two boilers will be required for this purpose, each about 26 feet long by 7 feet diameter, with two furnace flues and cross-tubes to each. Each boiler will be of sufficient power for doing the work of the whole establishment, so that one boiler will work on alternate months, while the other is at rest for cleaning, &c.

Birmingham has also two open-air swimming-baths at Cannon Hill Park and Victoria Park. If considered as a whole, income from the baths does not meet the expenditure. The amount received from all the bathing establishments during the past three years was 5,801*l.* per annum, but the annual working expenditure during the same period was 7,023*l.*

PETERBOROUGH CATHEDRAL.

THE Dean announces that the restoration of the north gable of the west front of Peterborough Cathedral is now completed. Those portions of the great arch and of the gable above it which have been taken down and rebuilt contained in all 2,006 facing stones. Of these 170 only were found so decayed that they had to be replaced by new ones; the remaining 1,836 have been put back again into their original positions. The scaffolding is being removed, and the completed portions of the work can now be seen. The result fully justifies the committee in the action which they have taken.

The central and southern gables, portions of which are in a very dangerous condition, will next be dealt with as the architect, Mr. J. L. Pearson, R.A., may advise, but for the completion of this work funds are urgently needed.

The Death is announced of Mr. Downwald Birch, an English painter who has lived for several years in Italy.

NOTES AND COMMENTS.

It is announced that a picture by MURILLO has been lying unnoticed in Copenhagen during several years. Originally it appears to have belonged to a church of the Jesuits in San Sebastian. The French commanders, who professed to confer liberty on Spain, carried off countless works from churches and convents, and the picture is supposed to have formed a part of the spoil of the invaders. It found its way to England, thence to Norway, and about 1820 obtained a refuge in Copenhagen. During its travels it could hardly fail to suffer, and the upper part has been restored by some northern artist who was unable to rival MURILLO in the use of glowing colours, and therefore preferred to treat his restoration in a style which cannot be mistaken. According to one French expert the picture is worth 24,000*l.* (which is 50 per cent. above the sum paid for *The Conception* in the Louvre), but the owner expects to receive 1,200,000 kroner for it.

THE awards of the jurors for the International Art Exhibition at Venice have been issued. The prize of the Municipality is to be divided. One-half (5,000 lire) is given to ETTORE TITO for his *On the Lagoon*, and the other half to A. MILESI for his *Wedding*. A part of the prize of 10,000 lire for foreign works, amounting to 5,000 lire, is awarded to LUDWIG DETTMANN for his *Evening of the Fête*; 2,500 lire go to OTTO SINDING for his *Winter Scene in Lofoden*, and a like sum to FRITZ THAULOW for his *Night at Sea*. The Italian Government's prize of 5,000 lire is equally divided between EMILIO MARILI, for a group in plaster, and A. ZORN, for a tavern scene. A sum of 2,500 lire, one-half of the prize of the Province of Venetia, is given to P. S. CROYER for his *Bourse at Copenhagen*, and a like sum to J. S. BASTIDA for *Blessing the Boat*. PIERRE BRAECKE obtains 3,000 lire for his group in plaster, *Forgiveness*, and G. ROMAGROLE 2,000 lire for his statuette *Ex Natura Ars*. The Murano prize of 2,500 lire is awarded to A. ZEZZOS for his *Venetian Girl* and other works. The prize of 2,500 lire offered by Herr LIEBERMANN, the painter, has been gained by V. BRESSANIN through his *Le Café*. A. MANCINI has obtained the Provincial prize of 1,600 lire by his *Meditation*. It will be observed that a British painter was not successful in securing any of the prizes.

SAINT-FRONT, Périgueux, we need not say, is one of the most important buildings in Europe if considered as an example of architecture on account of its plan and its cupolas. It was not, however, the scene of any important historic or ecclesiastical event, and therefore when we learn that the POPE has promoted Saint-Front to the dignity of a minor basilica we presume the reason was its architectural interest and antiquity. The sign of the distinction has been set up in one of the chapels. This is a pavillon or canopy made of red and yellow silk arranged in bands, with a globe of gilt copper on the top, which is surmounted by a cross which is likewise gilded. By the laws of heraldry the pavillon serves for the armorial bearings of kings and princes, the same purpose as mantlings for the arms of nobles, or, we venture to say, as the curtains and valance to be seen in exhibitions when it is intended to give importance to a picture or statue. When a cathedral becomes a basilica the insignia is carried in processions before the chapter, and should be preceded by a portable belfry, in which is a silver bell, which is kept ringing. The pavillon can also be introduced in the arms of the diocese, and the chief prelate has the privilege to wear the "cappa magna."

DICKENS has revealed the risks which can be incurred in England by becoming a trustee or the representative of a trustee. We suppose the examples put forth by the novelist have deterred the Combe Down Parish Council from accepting the sum of 200*l.* bequeathed by the late Mrs. ARABELLA ROXBURGH to aid in erecting a public reading and recreation-room. The lady's trustees do not consider they form a sufficiently responsible body to have charge of that particular sum, although they can carry out other conditions of the will, and they offered to transfer the duties imposed on them to the Parish Council. But, as Parliament neglected to introduce a clause in the Act which would

enable parish councils to accept legacies of the kind, the 200*l.* cannot be accepted by the Combe Down Council. Failing the Council, an offer has been made to one of the clergy to act. If an individual can legally accept charge of the money, it is remarkable that the trustees should be anxious to be relieved of their duties. They may be liable to an action for failing to act. Apparently Combe Down is likely to be in want of a recreation-room for many a day, and the case should be considered by the legislature.

BUILDING in Boston, U.S., during the past year was more extensive than was anticipated, for general business suffers there as elsewhere. The number of permits granted for first and second class buildings was 526; for third-class buildings, 1,975; for alterations, 2,331; for boilers, engines and heating apparatus, 1,552; and for plumbing, 4,442—the total being 10,826. The first and second-class buildings completed during the year numbered 388, and were valued at 9,088,000 dols. The third class buildings completed were 1,745 in number and cost 7,151,246 dols. The plumbing and repair work added to these made the grand total of the year's operations 19,906,849 dols. The construction of these buildings and improvements taxed the inspection force in spite of an increase of three additional plumbing inspectors and two additional building inspectors. The total number of examinations made by the force was 62,632, calling for 7,278 reports. The Building Commissioner advises that the inspection force be increased by three more plumbing inspectors and four building inspectors, three of the latter to be expert masons and two expert ironworkers. He also asks for the aid of two civil engineer architects, a request which seems reasonable in view of the fact that it was necessary to disapprove of 1,373 of the plans presented last year.

ACCORDING to the Latin proverb a great book is a great evil, and with busy men size has an influence on their judgment of treatises which are prepared for their special use. The "Price-Book for Approximate Estimates," just brought out by Messrs. SPON, is not much larger than a card-case, and can be made a *vade mecum* without spoiling a coat. As the information is arranged alphabetically it can be referred to instantaneously, and the prices are of the class which people who contemplate building are most likely to ask for when consulting with architects. Another small book, "The Science of Brickmaking," by Mr. G. F. HARRIS, F.G.S., and published by Mr. H. GREVILLE MONTGOMERY, is worth having; as it explains the nature of clays which are best adapted for conversion into bricks. The author has a talent for clear exposition. The lists of marks on timber published by Messrs. W. RIDER & SON, could not be better arranged or in a handier form, and they will be found invaluable to all who sell or purchase timber.

CATHEDRAL SERIES.—CANTERBURY: NORTH AMBULATORY, LOOKING WEST.—CRYPT, NORTH TRANSEPT.

BUSINESS PREMISES, ST. PAUL'S CHURCHYARD.

A LARGE block of buildings have recently been erected for Messrs. PAWSONS & LEAFS, with frontages to St. Paul's Churchyard, Godliman Street, Carter Lane and Dean's Court. The premises have a frontage of 200 feet in St. Paul's Churchyard, which, with Godliman Street front, is built in Portland stone, while the remaining two elevations are in Suffolk bricks, with Portland stone dressings. The main entrance is almost in the centre of the St. Paul's front with an arched head over. The building consists of ten floors, the majority of which are fireproof. The premises were erected in two portions, so as not to interfere with Messrs. PAWSONS & LEAFS'S business, and the whole of the works were carried out in a very short time.

The contract amounted to about 100,000*l.*, and was carried out by Messrs. PATMAN & FOTHERINGHAM, builders and contractors, of Park Street, Islington, and Theobald's Road, W.C. Mr. H. FORD, of 21 Aldermanbury, E.C., was the architect.

ST. PAUL'S CHURCH, BEDFORD.*

THE few notes which I have to offer and which have been rather hastily compiled must be mainly limited to the early state of things connected with the origin of this church. The church itself I shall only be too thankful to leave in the hands of the local friends who have so obligingly come to our support to-day, through the kindness of Mr. Hills. This subject is decidedly attractive; I only regret that I have not had more opportunity of investigating it.

This parish of St. Paul, which comprises the oldest portion of Bedford, is of unknown antiquity. It is certainly older than the parishes of the southern portion of the town, called Potter Street ward, because that was not added to Bedford till 1019, in the reign of Edward the Elder. It is a highly probable conjecture that the first Saxon church in Bedford, whenever it was erected, was dedicated either to the Apostle St. Paul, or St. Paul and St. Peter conjointly. Of such primitive dedications there are many examples. The proximity of this site to the most ancient localities renders it likely that the earliest Christian house of worship was situated here (on this spot). I am referring to the ancient ford and subsequent bridge, the Saxon fortress, where would be the residence of a thane or alderman, and the cheaping or market place, where the early borough moots would be held. But I must not pursue these speculations. What appears to be certain is, that the earliest associations of the church are monastic. Antiquaries agree that there was a primitive monastery here in the eighth century, and probably much earlier, under the Mercian rulers. King Offa II. had a partiality for it, and was perhaps a frequent visitor. There is reason for supposing that Abbot Alhmund, whose name is among the signatories to Offa's charter, given to St. Albans in 795, was Abbot of Bedford. However this may be, we have the authority of Matthew Paris for the burial of Offa with regal honours in a chapel at Bedford, 796, and the story of the subsequent submersion of the chapel and tomb by an inundation of the river Usca, *i.e.* the Ouse, and the complaints against Abbot Willelode for not securing his relics for St. Albans. The traditional site is, I believe, a few hundred yards up the river, opposite to Batt's Wharf. We may see this from the castle mount. It seems useless to speculate whether this chapel belonged to the monastery or to a royal residence. The monastery was probably destroyed in the devastations of the Danes, to whom King Alfred ceded this district north of the Watling Street, afterwards called the Danelagh; if so, however, it had been restored before 971, in which year Thurkytel was the abbot. He must have been of Danish extraction. The Saxon Chronicle informs us, under the year 971, that Oskytel, Archbishop of York, died at Thame on All Hallows' mass night (November 1), and Abbot Thurkytel, his kinsman, conveyed the body to Bedford—I suppose on its way for burial at York. This was in the reign of King Edgar, who was a great favourite of the monks.

We hear nothing more of the monastery; it was probably merged in the College of Secular Canons, which appears to have been established here a considerable time before the Conquest. Their church was dedicated to St. Paul, and very probably in succession to the church of the monastery. In the Domesday Survey, the canons of Bedford are named after the canons of St. Paul's, London (I am following the account given in Parry's "Illustrations of Beds"). They were a powerful body, well endowed with estates, and were lords of the borough manor. In their time a Norman church must have been erected, and I conjecture on this site. I may be treading on debatable ground in describing it as being situated just outside the western precincts of the Norman castle, which was erected here in the reign of William Rufus by Payne de Beauchamp, third Baron of Bedford. The distinguished antiquary, Mr. George Hurst, supposes the moat to have joined the river close to the present bridge, where the Swan Hotel now is. This church was on the canons' land, and clearly outside the castle. This secular college would have been governed by a dean or provost. About the time when the diocese of Lincoln was constituted by Bishop Remigius, who began to erect his Norman cathedral in 1080, the canons were unjustly deprived of some of their privileges by this unscrupulous prelate. Leland says:—"The prebendaries had their houses about the circuit of St. Paul's Church, and the names of two prebends remain, although their stalls be at Lincoln." Remigius seems to have appropriated two of the canonries, with their corpus prebendæ, or estates, to his cathedral. There are still at Lincoln two prebendal stalls, having attached to them the names respectively of "Bedford Major" and "Bedford Minor." Lysons states that in his time (c. 1820) a Mediæval house was standing in St. Paul's Square, held under a lease from the Chapter of Lincoln, and was supposed to have been a prebendal residence. In the reign of Henry I. these seculars were transformed into Canons Regular of St. Augustine, by Lady Roysse, the

widow of Payne de Beauchamp, who was thus accounted their foundress. The cloister and walled precinct which must have been erected for them would have been rather cramped for room in this situation. Whether these canons had the patronage of other churches in the town I have no information, but I have to note that three churches here were at a somewhat later period in the gift of the Austin Canons of Dunstable, *viz.* St. Mary's, to which they presented a vicar in 1216; the church of St. Peter, Dunstable, which stood opposite to St. Mary's, and that of St. Cuthbert, to the north-east of the castle site. Presentations to these in the thirteenth century are noted in the Dunstable Chronicle. The influence of the Black Canons must have been powerful in Bedford. The prior here, of course, had the tithes, and was bound to provide for the parochial ministrations by means of a secular priest or chaplain.

If the Norman church was on the same lines as the subsequent one (as I suppose), it was what may be called a double church (for such was the character of this structure before the modern additions). It had two naves and two chancels of equal length and width. If this is correct, I suppose the north member to have been the church of the canons, and the south one the church of the burgesses; the south chancel was probably the lady chapel. In 1164, the 9th of Henry II., the canons were still here, for in that year an incident which had important consequences occurred. The account is given by the chronicler Ralph de Diceto. One of the canons, Philip de Broc, committed homicide; when put on his trial before the king's justiciary, he behaved contumaciously. He appears to have claimed benefit of clergy, *i.e.* to be tried by the bishop's court. The account of the matter is by no means clear. It is stated when brought before the Archbishop (Thomas) he could not deny his offence. The issue was that he was deprived of his canonry and banished the realm for two years. Which court pronounced the sentence is not stated, but the chronicler says De Broc's trial gave occasion to the serious controversy between the bishops and the civil authorities on the trial of criminal clerks, which the king thought to have brought to a settlement by the Constitutions of Clarendon. We know the unhappy consequences which ensued in regard to Archbishop Thomas à Becket. Leland thinks that this occurrence was the cause of the removal of the canons to a new abode. The site was in the adjoining parish of Goldington, afterwards called Newenham, about a mile down the river. The removal, therefore, probably took place soon after 1164. It is certain that the benefactor who promoted this was Simon de Beauchamp. The chroniclers call him the son of Roysse de Beauchamp, but Mr. Elwes (in his interesting paper on the castle) has shown that he was probably her grandson (the dates require it). He was heir to the Barony of Bedford, but for some years his estates and castle were kept in the king's hands, because it appears he took the side of the ecclesiastics in the struggle between Archbishop Thomas and the king. In 1190 he recovered the governorship of the castle from Richard I. by the payment of a fine of 100 marks. What concerns us is that he was a liberal patron of the canons, and transferred them to more convenient quarters at Newenham. He probably built their church, for he was esteemed their founder. He died in 1207, the 9th of King John, and was buried in St. Paul's Church. This is an interesting point. His monument was in this church in the time of Leland, who says, "He lieth before the high altar in St. Paul's Church, with this epitaph graven in brass:—'De Bello Campo jacet hic sub marmore Simon, Fundator de Newenham.'" That monument probably no longer exists. On the slab which is reputed his memorial (now placed against the east wall of the chancel) there is no matrix for an inscription. This has been pointed out by the late Mr. H. Addington (in his able paper on Bedfordshire brasses). There are on the slab (which is 8 feet long) the indents of an engrailed Latin cross and two small shields above, but no place for an epitaph; it is probably later than 1207. I will venture to suggest that it may be the memorial of Simon's son, William de Beauchamp, who died in 1262.

To return from this digression. From this time I suppose the church to have become solely parochial, although Tanner disputes this; its history is not concerned with the canons except in the matter of the exercise of their patronage in presenting the vicars and upholding their rectorial rights in the chancel. It is probable that the Beauchamps had more to do with the structure than the canons or priors. I must hasten on. The deeds of the notorious Fulkes de Breaute belong to the history of the castle. As soon as he was put in possession here by King John in 1215 we are told that he laid sacrilegious hands on Newenham Priory and other religious houses for obtaining materials for his extensive works of fortification; for the same purpose, Matthew Paris tells us, he pulled down the church of St. Paul. This does not necessarily imply its total demolition; it is reasonable to suppose that its foundations remained. King John cared for none of these things, or, rather, he granted a license for the perpetration. The church continued in this ruinous condition until the capture of the castle after the famous siege, August 24,

* A paper read by the Rev. Henry Fowler at the visit of the St. Albans Archaeological and Architectural Society, and published in the *Heris Advertiser*.

1224. When the fortress was doomed to be destroyed and levelled, King Henry III. issued his mandate to the Sheriff of Beds about the disposal of the materials. One portion of the stones was assigned to the Prior of Newenham for the repair of his monastery; another portion to the Prior of Caldwell, the House of the Templars on the opposite side of the river, and another portion was set apart for the work of rebuilding of the church of St. Paul—"perfectioni operis ecclesiæ Sancti Pauli Bedfordiensis." It is inferred that the church was rebuilt a few years after the date 1224. We are now arrived at the history of the present structure, and the question what traces there are in it of this Early English building. I will leave this in the hands of the Bedford gentlemen who have so kindly offered to give us the benefit of their knowledge of an important local subject and of their familiarity with the works which have been undertaken here in recent times, and by which I may say that the beauty of the building has been greatly enhanced. I will just note that Mr. Elwes supposes the stone from the castle was mainly sandstone, quarried at Sandy, and that some of that stone may be detected in this church.

CASSIOBURY.

A PARTY of members of the Upper Norwood Athenæum recently visited Cassiobury, the seat of the Earl of Essex. The following description was read by Mr. D. McKay:—

Although my paper is only a brief one, I want to take you back in thought to some sixty years before the Christian era, when the land now known as Hertfordshire, Buckinghamshire and Berkshire was held by the British Prince Cassivellaunus, who ruled the tribe of the Catuvellauni, or Cassi. In the Welsh Triads and Bruts he figures as Caswallawn, and his adventures are narrated in a very romantic form, but we need not follow them to-day. St. Albans has been quoted as the great stronghold of the tribe, and Chauncy gives Cassiobury as the residence of their leader, and with his name he associates the derivation of the hundred of Cashio. Cassivellaunus was a warrior, and as he was ever anxious to extend his territory he was feared alike by friend and foe. Julius Cæsar paid his second visit in the year 43 before Christ; but after an incursion for some twelve miles he was called back to his ships, which a storm had damaged. The necessary repairs having been effected he sailed up the Thames and encountered Cassivellaunus and his army on the north bank; but notwithstanding all efforts of the Britons the Romans effected a landing. Their march was impeded by the 4,000 charioteers of Cassivellaunus, who was aided by several other native tribes. Cæsar, however, came to conquer, and one after another the Trinovantes and other tribes surrendered, praying Cæsar to protect them from their ally. Finally the British leader was compelled to yield, and for the rest of his life he paid tribute to Cæsar. In Cæsar's account he mentions having conquered the Cenimagni, Segontiaci, Ancalites, Bilroci and Cassi. Professor Rhys in his "Welsh Philology" suggests that the name Cassivellaunus is of Gaulish origin, and he gives the meaning as "a ruler of the league" or "a tribe king."

We now pass over eight centuries, and Offa is king of the Mercians. In a manuscript attributed to Matthew Paris, it is stated that his real name was Wilfreith, but owing to his likeness to his ancestor named Offa he changed his name. Of his doings for the first fourteen years after he ascended the throne no record remains, but in later life he evidenced a taste for war, and possibly, in atonement, he became a benefactor to the Church. At a synod held at Chelsea in 787 he was instrumental in establishing the Archishopic of Lichfield, and at the same meeting he introduced Peter's pence. He made grants to Christ Church and St. Augustine's at Canterbury, to Worcester, Peterborough, Rochester, Evesham and other churches. The greatest crime he ever committed was probably the murder of Ethelbert, king of the East Angles, who was afterwards canonised. On pretence of giving Ethelbert his daughter in marriage, he invited him to his palace and there beheaded him. In expiation of his crime he discovered the body of Alban, who had been martyred in 304; he journeyed to Rome and obtained the canonisation of Alban at the hands of Pope Honorius, and at Verulam he founded a monastery, which was dedicated to the proto-martyr. The abbot of St. Albans took precedence of all English abbots, and for his personal use Offa granted him the manor of Cassiobury, which was held in succession by fifty-one abbots, when Henry VIII. dissolved the monastery. In Domesday Book Cassiobury appears as Cassiou, and in an article by the Rev. H. Fowler, the name is variously given as Cayshobury, Casgeho, Caissou, Caishoo, Kayso, Cassio and Cashio. In the record in Domesday Book no mention is made of any church, although Watford Church is known to have existed in the eleventh century. I mention Watford Church because the manor of Watford is comparatively a new one, and originally formed part of Cassiobury.

In August 1546, for a consideration, Henry VIII. granted Cassiobury to Sir Richard Morison, who had acquired great honour as an ambassador to the Emperor Charles V. and other German princes. The abbot's manor house was built mainly of timber, and Sir Richard commenced to pull down, alter and extend it. On the accession of Queen Mary he fled to Strasburg and joined the exiled reformers. His son, Sir Charles Morison, carried on and completed the work of rebuilding. With the exception of the north-west wing the mansion was pulled down and rebuilt in 1677, Hugh May being the architect. Evelyn visited the new house, and described it under the date of April 18, 1680. As recently as 1800 the chief portion of the house was again destroyed, and the present pseudo-Gothic building was put up under the direction of James Wyatt. In his volume on Cassiobury John Britton states that part of the north-west wing of Morison's house was still preserved, and with it a portion of the abbot's house, and a chamber of May's building, which, with its handsome ceiling by Verrio, we have seen to-day.

Sir Richard Morison's widow, Bridget, became the wife of Henry, Earl of Rutland, and after his death she was married to Francis, Earl of Bedford. Her son, Sir Charles Morison, married Dorothy Clerk, and left a son, the second Sir Charles. He married a daughter of Viscount Campden, who built Campden House, Kensington, and left an only child, Elizabeth, who by marriage conveyed the estate to Lord Arthur Capel, Baron of Hadham. One of his ancestors was twice Lord Mayor of London, and his name is perpetuated in Capel Court. Lord Arthur was a staunch adherent of Charles I., and was beheaded in Palace Yard, Westminster. In response to his dying request, Bishop Morley, of Winchester, enclosed his heart in a silver box, and in due time handed it to Charles II., who in 1661 passed it on to the son and created him Viscount Malden and Earl of Essex. For alleged complicity in the Rye House Plot, the Earl was committed to the Tower and was there assassinated. Since then Cassiobury has had many owners who have left their names in history.

The entrance hall is a narrow cloister, whose Gothic windows are bright with coloured glass. On the walls and elsewhere various curiosities are displayed; possibly the most remarkable being the preserved head of a chief, brought to England in 1838 by Sir B. Capel and presented to Lady Essex. Near at hand is a Crimean War trophy, including a flag, brass musical instruments, swords, a helmet and guns, and not far away are the snow shoes worn by Papineau, the Canadian traitor, when he escaped from the British troops. In the great cloister, carpeted with deer skins from the denizens of the park, and now used as a billiard-room, portraits of Charles I., Queen Anne and Sir Thomas Conynsby with his dwarf Cricket are seen; and on an easel is an emblazoned panel-portrait of Henry IV., which he gave to Lenthal when he laid the first stone of Hampton Court, Herefordshire. The grand staircase is a splendid piece of wood-carving. The walls are covered with portraits—Moll Davis, the actress, by Lely, Lady Mary Sackville, George II. and Queen Caroline being among them. In the great dining-room, of old the chapel, where two brasses are let into the stone outside the window, the chief portraits are the Earl of Northumberland, by Vandyke; Algernon, Earl of Essex, and George, the fifth Earl of Essex, by Sir W. Beechey; Arthur Algernon, the sixth Earl, and Lady Elizabeth Percy, and her son and daughter, by Witting. In the saloon the ceiling is by Verrio, and, according to Evelyn, represents Apollo and the liberal arts. The green drawing-room, with its furniture of the Regency, its china, and its picture by Turner, is a striking contrast to the great library, which, with its bright flowers and fanciful decorations, is now a blaze of colour. Above the fireplace is some of Gibbons's carving, and busts of Russell, Althorp, Brougham and Denham are ranged about the room. In the smallest of the three surrounding libraries the most treasured relics of the house are contained. In one frame, covered by a silk curtain, are miniatures of Charles I. and Henrietta Maria, a piece of the blue ribbon of the Garter he wore when executed, and a scrap of the velvet pall which covered his tomb at Windsor when it was opened in 1813. In another frame is Conynsby's handkerchief stained with the blood of King William when he was wounded at the Battle of the Boyne. Here again the carving by Gibbons decorates the walls, and among the paintings is a portrait of Elizabeth Capel, Countess of Carnarvon.

In the inner library are portraits of Lord Arthur and his family, by Cornelius Jansen, and William, the third earl, and here is a scroll of fruit and flowers by Gibbons, which is almost unrivalled. According to an inscription on brass, the heart of Arthur, Lord Capel, is preserved in this room. In the gallery library is a portrait of the first Earl of Cork, who died in 1643. In the oak dining-room, with carvings by Gibbons, are various portraits—Robert Devereux, beheaded in 1601, by Vansomer; George Capel Conynsby, fifth Earl of Essex; Edward, the seventh Earl of Abergavenny, by Vansomer; the Earl of Ranelagh, by Lely; and Sir Joshua Reynolds, painted by himself. "The Catspaw," by Landseer; a portrait of Napoleon,

painted in 1815, the year of his last battle; and "Mrs. Freeke's Tea Party," by Hogarth, are also associated with this room. In a room specially set apart for the use of the younger members of the family is a quaint silhouette picture in black and bronze, representing a lad and lass of days gone by on horseback. The private office is panelled in red on a white ground; a Japanese inlaid cabinet of fanciful design and some quaint little pictures are among the most noteworthy features of the room. In her ladyship's boudoir the doors are decorated with miniature portraits, the work of Sarah, wife of the fifth earl. Among the pictures in this room is a portrait of the Duchess of Grafton, daughter of Lord Arlington, by Lely, and a celebrated painting by Rubens, representing Charlotte de la Tremouille, afterwards Countess of Derby, who became celebrated for her defence of Lathom House.

The park, which is divided by the river Gade and the Grand Junction Canal, consists of 700 acres, and is nearly four miles in circumference. The Home Park occupies 310 acres, the Upper Park 250 acres, and the remainder includes the pleasure gardens and other grounds surrounding the house. The park was planted by Moses Cook, who in his work on "Forest Trees" congratulates himself on having raised 296 of the limes from seed. The private gardens were laid out by Le Nôtre, who did like service at Versailles; and the Swiss cottages scattered about are the work of James Wyatt. Chestnuts, English and Spanish beeches that cover an area of 150 feet, elms, silver firs, the largest in the county, oaks, cedars from Lebanon, stone pines and tulip trees decorate the park. The willow by the Napoleon fountain came from his tomb at St. Helena; a treasured bay tree was grown from a cutting from the tomb of Virgil, and one tree now represented by a sapling was planted by Queen Elizabeth. On the edge of a dell, where trees and shrubs are allowed to grow at will, a dogs' cemetery has gradually been formed, and memorials, some of them with specially-written verses, have been placed to Poor Pilot, Dan Tucker, Viper, Rattler, Jock, Corrie, Peter, Tommy, Sam, Nelly, Muff, Fanny, Olga, Sailor, and other canine pets of Cassiobury. As we turn our backs on the picturesque red brick mansion, we tender grateful thanks to the genial Home Secretary, Sir Matthew White Ridley, and to the gracious Earl of Essex, George Devereux de Vere Capel, who have enabled us to spend a memorable afternoon.

Until the dissolution the church of St. Mary, Watford, belonged to the abbey of St. Albans. The rectory, with the patronage of the vicarage, was granted by Henry VIII. to John Lord Russell, afterwards Earl of Bedford, who in 1563 sold it to Sir Charles Morison, of Cassiobury. St. Katherine's Chapel, afterwards known as the Haydon Chapel, was destroyed in 1870 by Mr. Christopher, of Watford. In Keyser's list of mural paintings representations of St. Christopher and St. Dunstan are recorded as having been on the pillars between the nave and north aisle. In the vestry is a carved cupboard of continental make, presented by the Rev. R. Lee James, who carved one of the panels. The table is believed to have served as an altar. The Norman and Early English stones on the floor are from the earlier churches. On the north chancel wall are brasses to Hugo de Holes, who died in 1415, and his wife Marghetta, who died in the year following. The Essex, or rather the Morison Chapel, was built by Bridget, the Countess Dowager of Bedford, who died in 1600. In the centre of the chapel is an altar tomb of coloured marbles to herself and her three husbands. Beyond it is an altar tomb with six Tuscan columns to Lady Elizabeth Russell, who died in 1611. Against the south side is a monument to Sir Charles Morison the elder, who died in 1619. The sculptor was Nicholas Stone. In Horace Walpole's "Anecdotes" he quotes from Stone's diary where he states he received 260*l.* for the work. On the north wall is a monument to the younger Sir Charles, for which Stone received 400*l.* On the same side there is a monument to Lady Katherine Rotheram. The brass on the floor was placed by Dorothy Lady Morison to the memory of three of her servants.

STRUCTURAL TEMPLES.*

THE "structural temples" of the ancients as well as their rock-cut temples were all or nearly all built upon a common plan. This would seem to convey the impression that at one time a universal monotheistic system of religion prevailed, and that the changes in the system were but the natural result of the changed conditions under which the different peoples have existed.

The requirements of a temple were:—First, an adytum or cella. This was the most sacred place. Second, the inner court or the place where the priests officiated. Third, the outer court where the people were admitted. The foregoing requirements were not universal, as many small temples were erected with only a cella surrounded by a colonnade. Nearly all the

larger temples, the remains of which exist, were erected on the general plan above indicated. As in our former papers, we have been compelled to draw largely upon the civilisation of ancient Egypt for interesting matter, so in this we shall be compelled to go to that interesting country for the earliest examples of "structural temples."

The architectural history of ancient Egypt divides itself into three periods. The first of these is represented by the pyramids dating from the time of the Memphian kings, and are believed to be the oldest structures in existence. The second period is the one that has bequeathed to the world the indestructible magnificence of the ruins of Karnak, of Luxor, and of Medinet, and belongs to the Theban dynasties. The third has left behind it the temples of Hermonthis, of Kom-Ombos, of Khartos, of Edfoo and of Philæ, and represents the Ptolemaic rulers of Egypt. In the accounts which the Egyptians themselves have transmitted to us, their early history and chronology are divided by reference to the dynasties of their kings, of which dynasties they number twenty-nine. Their great epochs are:—The fourth dynasty reigning at Memphis, the pyramid builders; the twelfth dynasty, of which Osirtasu I. was the great monarch, and the eighteenth and nineteenth dynasties, which followed the expulsion of invaders known as the Shepherd Kings.

The early part of the eighteenth dynasty was rendered illustrious by the exploits of several kings, known under the name of Thothmes, Rameses III. The first king of the nineteenth dynasty is clearly identified as the conqueror known to the Greeks as Sesostris.

The eighteenth and nineteenth dynasties are the great builders to whom Karnak and its neighbouring temples are due. From the conclusion of this brilliant epoch Egypt began to decline until her misfortunes were consummated by the invasion of the Persian conqueror Cambyses, 525 B.C. A period of destructive tyranny followed until relieved by the enlightened policy of the Ptolemies. Architecture and arts were revived, never with the splendour of the national epoch, but still with much richness and tasteful variety. From the time of the twelfth dynasty we find Egyptian architecture characterised by the presence of obelisks and columns, both unknown to the earlier builders. The simplest form of Egyptian pillar was the plain square pier. Its next form is the octagon formed by cutting the angles off the square.

This same step carried further gives a sixteen to thirty-two sided figure, and then the idea seems to have been suggested of hollowing out the faces of this polygon with reversed curves, making a fluting; and we thus reach what is called from its similarity to a Greek order of that name, the proto-Doric column. A large class of pillars have what is called the "Lotus bud capitals," being an imitation of the buds of that sacred plant. Another large class is distinguished by Isis heads, or heads of Typhon, carved on its capitals. The earliest examples are in very low relief. It is probable that these ornaments were first simply painted on the capitals. Afterwards they cut the ornament in low relief, gradually improving on the design and its execution as the relief became higher, until its full development was attained as shown by the later examples of this work. The great palace temple at Karnak is perhaps the noblest structure ever built by human hands. Its principal dimensions are 1,200 feet in length by 360 feet in breadth, thus covering more than twice the area of St. Peter's at Rome. Its hypostyle hall or great court is 340 feet long by 170 feet wide, an area more extensive than that of Cologne Cathedral, thus giving standing room for nearly 40,000 persons. The original portion of this temple, or rather group of temples, was built by Osirtasu I., the great king of the twelfth dynasty. It appears to be the only structure left standing during the 500 years of the rule of the Shepherd Kings. It may have been pulled down by them and afterwards restored, as its great blocks of polished granite were nearly indestructible. On the restoration of the native dynasty, its first king, Amenophis, enclosed the earlier temple with a structure 120 feet square. Later Thothmes I. built in front of it a hall, surrounded by colossi backed by piers. With these additions the temple covered a space of 540 feet long by 280 feet wide, when the "sun worshippers" broke in upon the great eighteenth dynasty, and for a time checked architectural development. When the native race were again restored to power, Meneptha commenced the great hall which was nearly completed during his reign. Says a recent visitor:—"The hypostyle hall is the culminating point of the whole group of buildings. No one can describe its beauty, and no artist has yet been able to reproduce its form so as to give those who have not seen it an idea of its grandeur. The mass of its great central piers illumined by a flood of light from the clerestory, and the smaller pillars of the wings gradually fading away into obscurity were so arranged and lighted as to give an idea of infinite space, while the beauty and massiveness of its forms and the brilliancy of the coloured decorations make a wonderful *ensemble*, filling the mind with admiration and awe."

The ruins of Karnak are on the eastern side of the Nile. Across the river on the Libyan side the temple palace of

* A paper by Mr. Cyrus K. Porter, published in *Stone*.

Rameses III. crowns the rising ground of what is now called Medinet Abou. This is the latest of the four great temples of Thebes, and is by far the best preserved. "You enter," says a recent visitor, "through two pavilions which may have been originally porters' lodges, and passing through the court of Rameses (perhaps the private residence of the Pharaoh) emerge into a spacious area which leads to the great court of the temple. Here all the peculiarities of Pharaonic Egyptian architecture are displayed in the highest perfection, and bring most clearly to mind the spirit and genius of that wonderful people. It is, with the exception of Karnak, the most striking and magnificent interior in Egypt."

"The grave grandeur of this court," says Curtis, "is unsurpassed in architecture. Open to the sky above, a double range of massive columns supported a massive pediment. The columns upon the court were 'Osiride'—huge square masses covered all over with hieroglyphics, and with figures with folded hands carved in bold relief on the faces of the columns. The rear row was of circular columns, with papyrus or lotus capitals. The walls dimly seen behind this double colonnade are all carved with history, and the figures upon them and the architraves variously coloured."

This coloured decoration is indescribably effective here. Bas-reliefs in such limitless profusion would be objectionable, but these coloured intaglios, extending as they do over the whole building, give an ornamentation without impairing the outline or disturbing the general effect. They are cut down 3 or 4 inches deep into the solid stone, and their edges are as sharp as they were the day the workmen left them.

Coming down to the last, or Pharaonic, period of Egyptian architecture, we have only space to give a brief description of what is known as Apollinapolis Magna, or the temple of Edfu, about twenty miles south of Thebes. It is one of the largest in Egypt, and is in a comparatively good state of preservation. Its form is rectangular, and its general dimensions are 450 by 140 feet. In the centre of one of the short sides is the entrance, which consists of two buildings, each 100 feet long and 32 feet wide, both pyramidal in form and lying in the same direction, but separated by a passageway 20 feet wide with a doorway at each extremity. This passage conducts us to a quadrangle (outer court) 140 feet long and 120 feet wide, flanked by twelve columns on each side and eight more on the entrance side, all a few feet within the walls, thus forming a colonnade on three sides covered by a flat roof. At the further end of the quadrangle (reached by steps) opposite to the entrance is a portico extending the whole breadth of the quadrangle, and 45 feet in depth. It has three rows of columns, six to each row, covered by a flat roof, and is enclosed by walls on three sides, the fourth, or that opposite the entrance, being open.

This is, however, closed breast-high by a species of pedestal half-inserted in the columns, and in the central intercolumniation a doorway is constructed with piers, over which is a lintel and cornice cut through. From this portico a door leads to an inner vestibule with three rows of four columns, each smaller than those first described, but distributed in the same way. Beyond this are sundry passages with staircases and apartments, whereof the smaller one was probably the adytum. The present condition of this temple, as described by a recent traveller, may prove of interest. He says:—"The other temples of Egypt are either ruined or buried. In no single instance elsewhere can we see the temple in its original perfection, but here at Edfu the splendid building seems intact, perfect as when its architects left it. Except the cornice, the immense pylon is entire, and its position, with a space cleared in front and at the sides, gives it a commanding aspect that no other gateway in Egypt possesses. From every point of view the temple at Edfu is magnificent, whether standing on the steps that lead down from the modern to the old level, where one looks up to the smooth, creamy walls of the towering pylon, or, sitting under the colonnade of the great court, one surveys the dark entrance of the hypostyle hall, separated from the court by the low sculptured screen, like the choir of a cathedral, or wanders among the chambers around the sanctuary and along the paved corridor bounded by lofty sculptured walls. But perhaps the view which most delights the artist's eye is that which is obtained from near the sanctuary. Overhead rise the columns of the hypostyle hall. In front through a deeply-shaded vista of columns and portals appears the great court gleaming in sunshine, and through the gateway of the mighty pylon which closes the view, a vision of the outer world gives life to the scene."

Above the first cataract of the Nile is the sacred island of Philæ. The surface of the island is a mass of ruins, but the great Temple of Isis yet stands and a smaller temple overhangs the river. Two colonnades unite these temples. The western and more important of the two consists of thirty-three columns whose shafts are covered with intaglios and whose capitals ingeniously varied never repeat the same design.

Sixteen columns in less complete preservation form the eastern colonnade. About in the centre of the western gallery a flight of steps whose base is often under water cuts the con-

tinuous rampart and descends to the river. This propylon recalls the Roman epoch, and is not less beautiful for that. Everywhere the head of Augustus, the sceptical profile of Tiberius, or the brutal face of Claudius surmounts the great meagre figure carved with that uniformity from which Egyptian art never knew how to vary.

The temples of Philæ might easily be restored or at least further decay prevented, and let no one scorn these temples because of their comparative recent date. To the epoch of Rameses belong most of the colossi among Egyptian ruins, but the advent of the Ptolemies was a signal for a marvellous revival in arts and letters. What Egyptian architecture lost in massiveness it gained in graceful proportion.

Philæ has a history of its own, political and religious. The Pharaohs, the Ptolemies, the Cæsars in turn abandoned Philæ, but its gods remained and sustained the long siege of the new faiths. Osiris, oldest of Egyptian divinities, had his tomb in the sacred island, and with bated breath the Egyptian was wont to swear as his most solemn oath, "By him who sleeps in Philæ." Here was the home of Isis and Hather, and the sacredness of the place increased as the worship of its local divinities spread over the Roman world. Christianity came late to Philæ.

In the latter part of the seventh century of our era Isis still had her worshippers under the Egyptian palms.

About one thousand years before the dawn of the Christian era there was commenced in the city of Jerusalem a very important structure known in history as Solomon's temple. This may be regarded as the first attempt of the Hebrew people to erect for themselves a permanent place of worship. Heretofore the Divine presence had manifested itself and pronounced its judgments and promulgated its laws from the sanctum sanctorum of a temporary tabernacle. This tabernacle was for the first time set up in the plain at the foot of Mount Sinai; it was a movable temple and accompanied the hosts of Israel in all their wanderings in the wilderness of Arabia for a period of nearly forty years. From the time of its erection and consecration until the ark of the covenant was safely deposited within the adytum of King Solomon's temple this tabernacle, or one of similar form, served as a temple for the worship of the God of Israel.

The tabernacle itself was not a very large structure. In form it was rectangular, 45 feet long, 15 feet wide and 15 feet high. In front of it was a court or yard 150 feet long, 75 feet wide and surrounded by a screen 7½ feet high. It was so constructed that its parts could be easily taken down, packed into a small compass and transported from place to place. The long sojourn of the Israelites in Egypt, the fact that their chief employment there seems to have been the manufacture of bricks, must have made them acquainted with the architecture of that country. On the conquest of Canaan the Israelites seem to have taken possession of the dwelling-places of the vanquished people, and there appears no record of the erection of any important building till the days of Solomon. To this prince was delegated the important mission of carrying out the wishes of David, his father, in regard to the erection of a temple, but at so low an ebb was the art of building that the native workmen did not know even how to hew timber properly. The king therefore applied to Hiram, king of Tyre, with whom he was on friendly terms, and that monarch provided an architect and skilled workmen to carry forward the work. This building is described as a building of stone, roofed and floored with cedar. The temple itself was not a very large structure, being about 110 feet long by 36 feet wide by 55 feet high. In front was a porch the same width as the temple—36 feet—and about 18 feet high. On three sides were the priests' chambers three storeys in height. On the right side was a winding stair leading to the upper storeys of the chambers. The walls of the house as well as the ceiling were lined with cedar. The joists also appear to have been of cedar, but the floor was of planks of fir. At the door of the porch were two columns or pillars of brass or bronze, each about 33 feet high and about 7 feet in diameter. In front of the porch was the altar surmounted by a low wall, three courses of stone in height. The whole building was enclosed by a walled court called the inner court, or court of the priests. In front of this was another called the lower court, and the whole of this area was enclosed by a circumscribed court going around all the other courts and buildings, and this was called the outer court, or court of the Gentiles. Canina conceives the style of the building to have been Egyptian; that the temple was lighted like the hypostyle hall by a range of windows over the roofs of the cells or priests' chambers; that these windows were like those in the clerestory of a church, splayed at the bottom and sides; that the walls of the temple itself sloped toward the top on the outside, while the walls of the priests' chambers were built perpendicular.

He also supposes that the capitals or chapters, as they were called, which are described as lily work, were indeed the lotus or water-lily capital of Egypt. From the foregoing description it should be noted that the two celebrated pillars, Jachin and Boaz, which stood the one on the right hand and

the other on the left hand, were quite similar in their location and purposes to the columns or obelisks that occupied similar positions at the entrance of the Egyptian temple at Edfoo. We are told that the entire time occupied in building King Solomon's temple was about seven years and eight months, or about one-fourth the time occupied in erecting the legislative temple at Albany; that the occasion of its dedication and consecration was one of the most impressive ceremonies that the world has ever witnessed. "Israel sent forth her thousands and the assembled people beheld in solemn adoration the vast sacrifice of Solomon accepted. The fire descended upon the altar and consumed the offering. The shadow and glory of the eternal proclaims His presence between the cherubim, and the voice of His thunder told the faithful that the perfectness of their labour was approved."

Bright was the hour
When Israel's principals in their pride and power,
Knelt in the temple's court; the living flame,
The accepted sacrifice to all proclaim.
Brightly the splendour of the Godhead shone,
In awful glory from His living throne.
Then bowed was every brow, no human sight,
Could brave the splendour of that flood of light
That veiled His presence and His awful form,
Whose path the whirlwind is, whose breath the storm.

Without anticipating what we propose to say when we come to consider the Grecian and Roman orders of architecture, we will now turn to the consideration of some of the temples of ancient Greece and Rome. The early Greek temples did not have that graceful proportion which later characterised the works of Grecian architects and artists. One of the oldest Greek temples is the Doric temple at Corinth. The date of its erection has not been satisfactorily determined, but is supposed to belong to the age of Cypselus, or about 650 years B.C. In this example the columns are only about four diameters in height, and the architrave, which is the only portion of the entablature now remaining, is proportionately heavy. It is indeed one of the most massive specimens of architecture now in existence, more so even than the rock-cut prototype at Beni Hassan, Egypt, from which it was undoubtedly copied. As a work of art it fails from excessive strength, a fault common to most of the efforts of a rude people ignorant of the true resources of art and striving by the expression of physical power alone to attain its objects. Next to this in age is the temple at Ægina. Its date, too, is unknown, but judging from the character of its sculpture it belongs to the sixth century before Christ. Athens had a great temple on the Acropolis contemporary with the foregoing, and portions of its columns still remain which, after its destruction by the Persians, were built into the walls of the citadel. It is probable that all the cities of Greece had temples commensurate with their dignity before the Persian war. Many of these were destroyed in that struggle, but it also happened, as in France and England during the twelfth and thirteenth centuries, that the old temples were thought unworthy of the national greatness and of that feeling of exultation arising from the successful result of the greatest of their wars, so that almost all those that remained were pulled down or rebuilt. The consequence was that all the great temples now found in Greece were built in the forty or fifty years that succeeded the defeat of the Persians at Salamis and Platea. The oldest temple of this class is that known as the Theseum, or Temple of Theseus, at Athens. It constitutes a link between the archaic and the perfect age of Grecian art, more perfect than the temple at Ægina or any that preceded it, but falling short of the perfection of the Parthenon, its near neighbour both in locality and date.

Of all the great temples the best and most celebrated is the Parthenon, the only octostyle Doric temple in Greece, and in its own class undoubtedly the most beautiful building in the world. It is true it has neither the dimensions nor the wondrous expression of power and eternity inherent in Egyptian temples, nor has it the variety and poetry of the Gothic cathedral, but "for intellectual beauty, for perfection of proportion, for beauty of detail, and for the exquisite perfection of the highest and most recondite principles of art ever applied to architecture, it stands utterly and entirely alone and unrivalled—the glory of Greece and the shame of the rest of the world." This beautiful temple was 227 feet long by 101 feet broad. Next in size and beauty was the Temple of Jupiter at Olympia, finished two years later than the Parthenon. Its dimensions were nearly the same, but having six columns in front instead of eight as in the Parthenon; the proportions were different, it being 230 feet long and 95 feet wide. To the same age belongs the exquisite little Temple of Apollo Epicurius at Bassæ, 125 feet by 47 feet, the Temple of Minerva at Sunium, the greater Temple of Rhamnus, the Propylæa at Athens, and indeed all that is greatest and most beautiful in the architecture of Greece. The influence of Greek art was also felt in the island of Sicily, which was originally occupied by a Greek colony. The one city of Selinus had no

fewer than six temples in two groups, three in the citadel and three in the city. The oldest is the central one of the first-named group, and its sculpture indicates that it was erected soon after the foundation of the colony, or about 636 years before Christ. The most modern is the great octostyle temple, which seems to have been left unfinished at the time of the destruction of the city by the Carthaginians, 410 years before Christ. It measured 375 feet long by 166 feet wide, and was consequently very much larger than any temple of its class in Greece.

At Agrigentum there are three Doric temples, two small hexastyles built from 500 to 480 years before Christ, and one great exceptional example differing in its arrangements from all the Grecian temples of the age. Its dimensions are 360 feet long by 173 broad, and consequently very nearly the same as those of the great temple of Selinus just alluded to. Its date is perfectly known, as it was commenced by Theron 480 B.C., and left unfinished seventy-five years afterward, when the city was destroyed by the Carthaginians. At Syracuse there still exist the remains of a very beautiful temple of this age, and at Eggesta are the remains of another in a much better state of preservation. Pæstum, in Magna Græcia, could also boast of a magnificent group of temples. All of the foregoing temples are in the Doric order, and represent the earliest type of Greek art. The Ionic order, which to a certain extent superseded the Doric, does not present as many nor such notable examples as did the Doric order. Fergusson says:—"The recent discoveries in Assyria have proved beyond a doubt that the Ionic was even more essentially an introduction from Asia than the Doric was from Egypt. The only question is when it was brought into Greece."

The oldest example in Greece was probably the temple on the river Ilissus, dating from about 484 B.C. Next to this is the little gem of a temple dedicated to the Wingless Victory, and about fifteen years later was built the Propylæa at Athens. The last and most perfect of all the examples of this order is the Temple of Erechtheus on the Acropolis of Athens. Its date is apparently about 420 B.C., the great epoch of Athenian art.

If any temple in the Asiatic Greek colonies escaped destruction in the Persian war it was that of Juno at Samos. It is said to have been built by Polycrates, and appears to have been originally of the Doric order. The ruins now found are of the Ionic order. The temple was 346 feet long by 190 feet wide, and probably was built on a foundation of a former temple. More remarkable even than this was the celebrated Temple of Diana at Ephesus, said by Pliny to have been 425 feet long by 220 feet wide. Recent excavations on this site, however, prove that the dimensions apply only to the platform on which the temple stood. The temple itself measured from the outside of the angle pillars was 341 by 164 feet, about the average dimensions of our Mediæval cathedrals.

The Corinthian order was never used extensively by the Greeks in the erection of their temples. The largest example in Greece was the Temple of Jupiter Olympus at Athens. Though erected on Grecian soil it was essentially a Roman building, having been commenced in its present form under Antiochus Epiphanes in the second century before Christ by the Roman architect, Cossutius, and only finished by Hadrian, to whom probably may be ascribed the greatest part of what now remains. Its dimensions are 354 feet long by 171 feet wide, being nearly the size of the great hypostyle hall of the temple of Karnak. From the number of its columns, their size and their beauty, it must have been the most beautiful Corinthian temple in the Old World.

"There is nothing," says Fergusson, "that strikes the inquirer into the history of Rome more than the extreme insignificance of her temples as compared with other buildings of the Imperial City and with some contemporary temples found in the provinces." The only temple that remains at all worthy of such a capital is the Pantheon. All others are now mere fragments, from which we can with difficulty restore even the plans of the buildings, far less judge of their effect. Of the Augustan age we have nothing but the remains of three temples, each consisting of only three columns. The most remarkable of these was the Temple of Jupiter Stator in the Forum, the beautiful details of which are familiar to every student of architecture. This temple was octostyle in front. It was raised on a stylobate 22 feet in height, the extreme width of which was 98 feet, and this corresponds as closely as possible with 100 Roman feet. The angular columns were 85 feet between centres. The height of the column was 48 feet, and that of the entablature 12 feet 6 inches.

The temple nearest to this in situation and style is that of Jupiter Tonans, or the Temple of Saturn. It is much smaller than Jupiter Stator and of inferior design and execution. Its extreme dimensions are about 85 feet long by 70 feet wide. The next class of temples, called pseudo-peripteral (those in which the adytum occupies the whole rear part) are generally more modern; certainly more completely Roman than those referred to above. One of the best examples of this class of temples is the Temple of Antoninus and Faustina, a small building

measuring 120 feet long by 72 feet wide. The finest example of this class of temple now remaining to us is the so-called Maison Carrée at Nîmes, which is indeed one of the most elegant temples of the Roman world. It is hexastyle, that is, six columns in front with eleven columns on each side, three of which stand free, the remaining eight being attached (engaged) to the walls of the adytum. The temple is small, being only 85 feet long and 45 feet wide, but such is the beauty of its proportions and the elegance of its details that it strikes every beholder with admiration. The Temple of Diana in the same city is another edifice of singular beauty of detail, unsurpassed for variety and elegance by anything found in the metropolis, and applied here with freedom bespeaking the presence of a Grecian mind even in this remote corner of the empire. More perfect and more interesting than any of these is the Pantheon, which is undoubtedly one of the finest temples of the ancient world. Externally its effect is very much destroyed by its two parts, the circular and the rectangular being so dissimilar in style and so incongruously joined together. The portico especially, in itself the finest which Rome exhibits, is very much injured by being prefixed to a mass which overpowers it and does not harmonise with any of its lines. Internally, perhaps the greatest defect of the building is a want of height in the perpendicular part, which the dome appears to overpower and crush. This defect is aggravated by the lower part being cut up into two storeys in height, an attic being placed over an order below. Notwithstanding these defects, there is a grandeur and simplicity in the proportions of this great temple that render it one of the finest and most sublime interiors in the world. The dimensions of its dome, 145 feet 6 inches in diameter, with a height of 147 feet, have never yet been surpassed by any subsequent erection. Though it has been deprived of its bronze covering and of the greater part of those ornaments on which it mainly depended for effect, still nothing can destroy the sublimity of a design so vast and of a form so simply grand. It possesses, moreover, one other architectural peculiarity in having a single window, and that placed high up in the building. "I know," says Fergusson, "of no other temples which possess this feature, except the great rock-cut basilicas of India. In them the light is introduced even more artistically than here, but nevertheless that one great eye opening upon heaven is by far the noblest conception for lighting a building to be found in Europe."

Our paper on structural temples would be incomplete without a reference to the temples of Baalbec. The origin of the city of Baalbec is lost in remote antiquity. By some it is supposed to have been founded by Solomon, king of Israel, but I have not been able to find any reliable proof that such was the case. It was at one time the centre of trade and while under the control of the Romans was a very popular and important city. It was probably during the Roman occupation that the temples whose ruins now occupy the site of the city were erected. The style of the architecture indicates Greek art and Roman influence.

The group consists of the remains of three temples, usually known as the Great Temple, the Temple of Jupiter; of Apollo, or the Sun; and the Circular Temple. The Great Temple, which would seem at one period to have been a kind of Pantheon, is situated on a magnificent platform which raises it high above the level of the ground and extends from east to west a distance of 1,100 feet. The portico is at the eastern end and must have been reached by a grand flight of steps. It is 180, or, including the pavilions, 260 feet from north to south. A threefold entrance leads into the first court, which is hexagonal in shape and measures 250 feet from corner to corner. A portal 50 feet wide, flanked on each side by a smaller aperture 10 feet wide, gives admittance to the great quadrangle which extends from east to west 440 feet and has a breadth of 370 feet, thus enclosing an area of between three and four acres. On all sides except the eastern, where the stairs lead up to the front, the court was surrounded with an exedra of various dimensions enclosed by costly pillars and adorned with numerous statues, but statues and pillars and steps are now involved in a common confusion. The peristyle of the temple proper was composed of fifty-four columns, the front line consisting of ten and the side lines of nineteen each. The height of the shafts was about 62 feet, and their diameter 7 feet at the base and 5 feet at the top. They were crowned with rich Corinthian capitals, and supported an entablature of 14 feet in height. Most of them were formed of three blocks united without cement by strong iron dowels. Only six of these columns are still standing. That part of the platform on which the peristyle rests consists of immense walls built up about 50 feet from the ground, and formed, as may easily be seen on the northern side, of thirteen courses of bevelled stone in alternate layers of longer and shorter blocks. Outside these walls, at a distance of 29½ feet, is another wall on the north, the west, and probably, though concealed by the rubbish, on the east side. This is built up of large stones, and contains three blocks of such extraordinary proportions that the temple acquired from them the name of Trilithon, or three-stone temple. These measure respec-

tively 64 feet, 63 feet 8 inches and 63 feet in length, and are 13 feet in height, and have been raised 20 feet from the ground in the western wall. Two underground passages, 17 feet wide and 30 feet high, run from east to west along the sides of the platform of the great quadrangle and are connected by a transverse tunnel of similar description. They seem from the inscriptions on the wall to have been tenanted at some time by Roman soldiers.

Slightly to the north of the Great Temple and agreeing with it as to the points of the compass is the Temple of the Sun, which is in much better preservation than its neighbour, and though small in comparison with it is larger than the Parthenon at Athens.

It was also built on a platform and was reached by a flight of steps on the eastern end. The height of columns, including capitals, is 45 feet and the circumference of each 19 feet. They supported an entablature 7 feet high, from which a ceiling was carried back to the wall of the adytum, consisting of slabs enriched with sculpture of great beauty. The principal ornament of each slab is a hexagonal moulding enclosing the figure of some god or hero; but the profusion and elegance of the fretwork can only be rendered by the artist. After passing the vestibule the visitor reaches an exquisitely carved doorway (having a staircase on each side leading to the top of the building) which gives entrance to the interior of the temple.

On the soffit of the vestibule is the figure of an eagle, referred to by many travellers and regarded by Volney and others as the emblem of the Sun god. The adytum was richly ornamented, the floor now presenting a mass of broken sculpture and pillars.

Further east stands the Circular Temple, which is very small but of beautiful workmanship and design. The ruins of Baalbec have awakened the admiration of European travellers from the sixteenth century down to the present date. The city of Palmyra, the ancient Tadmor of the wilderness, is also noted for the ruins of its temples. The site of the city was long unknown until the spot was at last penetrated by some European travellers. It had an immense temple dedicated to the Sun, of which sixty-nine columns out of three hundred remain standing. Of its appearance in modern times, Volney observes:—"In the space covered by these ruins we sometimes find a palace of which nothing remains but the court and the walls; sometimes a temple whose peristyle is half thrown down, and now a portico, a gallery, a triumphal arch. If from this striking scene we cast our eyes upon the ground, another almost as varied presents itself."

"On whichever side we look the earth is strewn with vast stones half buried with broken entablatures, mutilated friezes, disfigured reliefs, effaced sculptures, violated tombs and altars defiled by the dust." In addition to the structural temples already described there are several very large ones in India and China. Enough has been said, I think, to establish the fact that a similar form of worship prevailed among the nations of antiquity, and that these forms required buildings of a similar construction to adapt them to the systems of ancient worship.

Another thing seems to have been pretty well established, and that is the construction of a secret vault or vaults beneath the adytum, or sanctum sanctorum, as a place of deposit for sacred vessels, of jewels, of gold and silver. We are told that a place of this character was built beneath the sanctum sanctorum of King's Solomon's temple, and that a true copy of the Book of the Law—that is, the Ten Commandments—with a history of the children of Israel up to that time, a true imitation of the ark of the covenant, and other valuable relics were deposited in that secret vault. We know that General Cesnola, who conducted the explorations of an ancient temple in the island of Cyprus, did discover such a secret vault, and from thence brought forth a large and valuable collection of ancient jewellery, which collection is now on deposit in the Museum of Fine Arts in Central Park in the city of New York. Such being the facts, we have no reason to doubt that if a thorough system of exploration were permitted, and was conducted upon scientific principles, very many valuable relics of art now hidden would be recovered, and the world largely enriched by the knowledge thus obtained.

The Local Government Board having declined upon second solicitation to allow the Scarborough Corporation to sell part of the Weaponness estate for the purposes of a site for a proposed Wesleyan College, Mr. J. H. Moody, a member of the Council, and the town clerk (Mr. J. E. T. Graham) have been appointed to wait upon the Local Government Board to endeavour to induce that authority to permit the sale upon the terms proposed, which are:—(a) For the first ten years the purchasers to pay the Corporation a rental of 5% per acre per annum; (b) from and after the expiration of that period the purchasers to pay in perpetuity a rental at the rate of 20% per acre per annum.

TESSERÆ.

Classification of Temples.

THE buildings and sites dedicated to Pagan worship were classified as *templum*, *ædes*, *fanum*, *delubrum*, *ædícula*, *tesca*, *sacellum* and *lucus*. The *templum* was not invariably a building, but sometimes a walled enclosure, either consecrated for worship or merely inaugurated for some public usage—thus were the *Curia Hostilia*, the *Curia Julia* and even the *Rostra*—classed among *templa*; the *ædes* was, in the exclusive sense, a sacred edifice, the “church” of Pagan worship, always consecrated, whilst the former might be without such dedication, though inaugurated. The *fanum* also might be merely a space marked out by the Pontiff for sacred uses, and the *delubrum* (as to which term grammarians differ) was probably an edifice where, under one roof, the images and worship of different deities had their centre. The *ædícula* was a small isolated shrine or niche, usually within a temple, raised for private piety, without formal consecration by the priesthood; the *tesca*, a shrine or tabernacle apart from other buildings; the *sacellum*, a chapel containing an image of some deity, without portico, and sometimes without roof; the *lucus* being a sacred grove dedicated to a particular deity, as were several in the Roman neighbourhood—one to *Picus* and *Faunus* (between *Ostia* and *Ardea*); another, near *Aricia*, to *Egeria*; to *Mercury* on the *Applan Way*; to the *Bona Dea* (or *Fauna*) near *Albano*; also the well-known grove of the *Camænæ* (Muses) near the *Porta Capena*. One sole example of the Pagan *ædícula* still extant in Rome is a small brick rotunda, with niches, on the *Applan Way*, between *S. Sisto* and the *Porta S. Sebastiano*. In the countless *Madonna* shrines of the city's streets we see the antique *tesca* faithfully reproduced.

The Villa Livia.

In the course of the explorations, under the direction of Signor Gagliardi, on the site of the *Villa Livia* or *Villa Cæsarum*, about eight miles from Rome, the workmen came in May 1863, on a flight of steps which led to two apartments about 20 feet under ground: one vaulted, divided by a wall, the other about 35 feet square, adorned with perhaps the most beautiful ancient frescoes hitherto brought to light. The ceiling of this exquisite apartment was principally composed of marble. When discovered, the centre was filled with marble fragments and rubbish, but so little damp existed that, with the exception of two or three places of insignificant extent, all the frescoes were as fresh as if they had just been painted. It is supposed that this part of the villa was situated in the midst of a plantation or garden, and that this painted room was intended to be in harmony with the objects around. The lower portion of the walls, to the height of about 4 feet from the floor, represents trellis-work, from which spring the most exquisitely painted trees, shrubs and plants. These are loaded with fruit and flowers, among which a variety of birds and insects are feeding, fluttering, or reposing. The vegetation is for the most part tropical, and the painter has been careful to introduce amidst it those animals only which are natives of tropical regions. The grace and delicacy of the foliage and fruit are worthy of Raphael's happiest efforts; indeed, it may be doubted whether any part of the famous paintings by that artist in the Loggia of the Vatican are more beautiful than these. Amidst the foliage is the representation of an elegant cage suspended from a bough containing a goldfinch, the bird being in all respects most life-like. The artist evidently bestowed very great pains on the adornment of this chamber, which antiquaries are disposed to believe was the garden bower of the voluptuous *Livia*. As the paintings are in a villa built for *Livia* by Augustus, it is but reasonable to conclude that they are of that period, and were painted by *Ludius*. They are in all respects worthy of that artist, for they far surpass paintings of a similar nature hitherto found at Pompeii. No feature is neglected, every portion is painted in a manner exhibiting the most intimate acquaintance with the trees and flowers represented, and the same may be said of the various birds and insects which are introduced.

The Gothic Revival.

The great impetus to the revival of art in England was given by a religious movement. It was when the deficiency of church room in proportion to a rapidly-increased population had roused the energies of the Church of England that people felt the need of a working knowledge of ecclesiastical architecture. For nearly three centuries church building had been almost unknown in England. After the excesses of the Reformation, and the still more destructive iconoclasm of the Great Rebellion, enough churches remained for all the wants of the rural, if not of the urban population. Pointed architecture for religious buildings died out quite as much negatively, from want of occasions of exercise, as positively from the superior attractions of revived Italian. What works of church building and church restoration were undertaken in the seventeenth century were almost intended to be in the old

style. Under *Laud* and *Cosin* there was even a temporary revival, and there are many churches, such as *Higham Ferrers* in *Northamptonshire*, *Probus* in *Cornwall* and *Castle Hanley* in *Worcestershire*, where very late work exhibits, in spite of defective detail, the general feeling of the *Pointed style*. So, too, the hall at *Lambeth Palace*, rebuilt by *Juxon*, is in its outline and proportion a Gothic building, as *Pugin* was fond of asserting, although the particular features are of an exceedingly debased kind. In the two universities, and in many cathedral cities, the actual practice of Gothic survived to our own days. It could scarcely be otherwise in places where so many noble examples of the style remained to influence successive generations of students or worshippers by their own mute eloquence. And the surveyors and workmen attached to most cathedral churches simply handed down, without breach of continuity, the traditions of their predecessors. So, too, it has been remarked by *M. Rio* that the *Duomo* of *Milan* has itself maintained, down to very recent times, a series of by no means contemptible Gothic designers. Domestic *Pointed*, again, though in a degenerate form, is not even yet extinct in many rural districts of England—along the *oolitic range*, for example, or upon the millstone grit, or, in short, wherever good building stone is easily procurable. Mullioned windows, bold labels and string-courses and well-worked chimneys are to this day living traditions among country masons in places where stone has not been superseded by the cheaper brick. It is only in the red-brick region of the Midland counties, and the domain of the still less picturesque white brick of *East Anglia*, that any remains of Gothic treatment will be sought for in vain. To these circumstances we probably owe the fact that, when church building became recognised as one of the most pressing duties of the age, it was taken almost as a matter of course that Gothic was the prescriptive style for ecclesiastical architecture. In fact, there was no serious rivalry. The adoption of the *Pointed style*, in some form or other, was all but universal, and just enough opposition was made by the adherents of Greek or *Palladian* to give the *éclat* of a controversial victory to the supremacy of Gothic. Here and there, indeed, a church was built in pseudo-Classical style. *Pennethorne*, for instance, inflicted upon London the nondescript monstrosity of *Christ Church* in *Albany Street*. At *Wilton* and at *Streatham*, though thoughtful in plan and sumptuous in execution, premature attempts were made to import foreign forms of undeveloped Gothic without any attempt to mould them to the national type.

The Pre-Raphaelite Reaction.

Pre-Raphaelitism in its origin was a natural and necessary reaction from a system of effete conventionalism. And in so far as it vindicated the necessity of truthfulness and reality, of the original study of nature, and of the due attention to the inner meaning of art, it deserved sympathy. Unhappily, if not the leaders yet the followers of the movement carried their reaction too far. Passing beyond the true mean in the opposite direction, they came to subordinate the ideal to the actual, and in their pursuit of the minute accuracy of accessories they forgot alike abstract beauty and general harmony of effect. The extraordinary finish of Dutch art in the genre style, in which the labour of half a lifetime was expended on a pot or a pan, a carrot or a carpet, had begun to be estimated at its right value as a waste of time and thought on unworthy subjects. But the new school were ready to elaborate with nearly equal minuteness the grass or flowers of the field or the pattern of a brocade without observing that due proportion, that balance of light and colour which was never absent from a *Mieris* or a *Douw*. All details, whatever their relative prominence in nature, were, so to say, equally accented. The softening, mellowing, blending, obscuring effect of atmospheric distance was by some of these artists ignored altogether. Because aerial perspective had been abused and made to cover by a touch of hand a multitude of sins of omission and carelessness, the new school painted their subjects as though they were all under the exhausted receiver of an air-pump. Because the conventional treatment of the middle distance had become an academic commonplace, it was thought original and meritorious to project a group like a coloured elevation on one plane, while each subordinate detail was made as independent and as prominent as though it were the special object of a microscopical observation. As a natural consequence, finish of execution and conscientious truthfulness of representation came in time to supersede the ideal conception of beauty. If a model was exactly copied its faults were perpetuated as much as or more than its good qualities. And thus many who were fully prepared to admire and to sympathise with the movement were revolted by a crudeness and often a repulsiveness for which the evident good intentions of the artists and their undoubted power as colourists and draughtsmen were no compensation. However, what amount of truth there was in the new principles has already had its victory. We owe to the so-called pre-Raphaelites a growing sense among our English school in general of the importance of the true mission of art and of the necessity of reality and patient fidelity in the imitation of nature.

Greek Architecture.

In architecture as in sculpture, in the form of a temple as in that of the deity to whom it was consecrated, a beautiful type once selected was respected and improved for ages by successive emulation, but never wantonly or capriciously abandoned from mere thirst for change or the pride of originality. The simple proportions of the wooden building in which their ancestry had worshipped remained in their marble temples under every subsequent modification, whether enriched with Doric, Ionian, or Corinthian ornament, whether bounded by a simple portico or a basement enriched with a surrounding peristyle of 100 columns. Appropriate decorations and proportions soon were attained in each of the prevailing orders; but, admitting within certain limits the variations required by the local situation of each separate structure, the main principle was adhered to. Perhaps there are not two of the edifices which exactly correspond with each other, and yet the diversity never seems to have been capriciously invented. Columns and friezes, blocked out within prescribed dimensions, were completely finished from scaffoldings after the temple was built, and the precise degree of diminution in the flutings, capitals and entablature were probably determined by the eye of the architect under circumstances which then enabled him more exactly to appreciate the effect. With him—as with the painter and the poet—“*Quidlibet audendi semper fuit æqua potestas*”; and yet all of them were restrained from unmeaning and random innovation. It was, indeed, only by these governing principles, which are alike essential to every one of the liberal arts, that they controlled the flight of genius; and it has been by neglecting these for the narrower rules of technical dogmatism that our failure has been rendered so conspicuous. The very axioms which Horace collects for poetry are equally applicable and have been equally violated in this kindred art. In her productions too “*desinit in piscem mulier formosa superne*”—in them too, with vain ambition and in discordant succession, “*latè qui splendeat unus et alter assuitur pannus*,” in many a form of motley plagiarism.

Invention in Painting.

Invention as a general power undoubtedly depends on the command of a large fund of ideas and an intuitive readiness of associating and combining them in every possible mode. This produces those radiant recollections by which the images of absent things are often almost involuntarily called up, with all the vivacity of real objects moving about us and pursuing us as in a kind of waking dream. Thus the casual mention of the single word battle will to some minds instantly furnish out an endless chain of associated circumstances; cannons roar, clouds of smoke arise, the combatants on each side present themselves, we see them rush together, fight, struggle and die; we hear their screams and shouts, notice all their various movements and changes of colour, advert to all the surrounding objects, observe how they are affected, and share their hopes, fears, compassion, rage, astonishment or despair. To an Englishman of warm feelings and a lively fancy the word would perhaps suggest a different train of associated ideas, connected with another element. His imagination would present the picture of a sea-fight in all its accumulated horrors—of ships sunk or blown up, batteries silenced and whole fleets of the enemy at one stroke taken or destroyed; it might transport him instantly to Copenhagen or the banks of the Nile, and force him to dwell with an equal mixture of grief, fondness and exultation on the unparalleled deeds and the untimely fate of the hero of Trafalgar. As a technical power invention consists, not in composing, in the first instance, the story to be represented, but in seizing at once on the peculiar and prominent feature of the subject, placing it in the noblest and most interesting point of view, taking in all that belongs to the time and place chosen, discriminating the characters, entering into their situations, circumstances and relations; and all this with a reference at the same time to the genius and powers of the art by which they are to be embodied. The painter, for instance, as soon as his mind is affected by the grand or the pathetic, instantly clothes his ideas in all that is touching and awful to the sight, and carries it out through the whole of his composition, which includes the invention and disposition of every part, the managing his background, throwing his lights and shades, and ordering the attitudes and action and expression of every figure that enters into and constitutes a part of his work.

Thorvaldsen and Scott.

Though Sir Walter Scott does not seem to have felt any especial interest in works of art, judging at least from the fact that he never once visited the Vatican during his stay in Rome, he was extremely anxious to make Thorvaldsen's acquaintance. The meeting between these two great personages must have been a strange one. Though Sir W. Scott was acquainted with several languages, he could speak none but his own, while Thorvaldsen knew nothing of English. But there was one language common to both of them, and that was the

language of the eye and heart. To have seen them pressing each other's hands, patting one another on the shoulder, nodding, smiling, while the only words that were heard on either side were “*connaissance*,” “*charmé*,” “*plaisir*,” “*heureux*,” “*piacere*,” “*happy*,” &c., must have been diverting in the extreme. The interview of course could not be of long duration. On separating they warmly embraced, and followed each other with their eyes as long as possible, “*darting at each other glances of the warmest assurances of regard and esteem*.”

A. W. Pugin on his Contemporaries.

Trading, under the cloak of art, belongs to the modern architects or surveyors—for the terms are now synonymous—men, for the most part, utterly despicable, who venture to profess a noble art for the sole purpose of prostituting and degrading it to their own private interests; and they have so far succeeded that, while immense fortunes have been amassed, their very name has almost become a reproach; men without one particle of soul or feeling except the hope of gain or the fear of loss. They proceed to design a church, a poor-house or a tavern in the same business sort of manner. They have a set of stale ideas drawn from borrowed sources, which they keep as stock patterns and transpose to serve all purposes. They do not understand any style, but profess themselves masters of all; and they will undertake any absurdity to suit the caprice of an individual, provided they are well paid. I never behold one of those sprucely-dressed, ignorant, insolent pretenders without a bitter rising of bile on hearing the careless manner with which he speaks of the greatest efforts of ancient art, cloaking his ignorance of their merit by an affected indifference. Show him a splendid piece of sculpture, and he will talk of the material out of which it has been carved; tell him of some vast cathedral, he will ask if it proved a good job for the contractor. The superficial contents of a brick wall or plastered ceiling, on which he gains as much a square rood, is of infinitely greater interest to him than the most elaborate production of an artist. In fine, he draws, looks, thinks and lives at so much per cent. This is the very acme of his ideas, and he would estimate the Raphael Cartoons by the yard, canvas included, and gird the limbs of Michel Angelo's *Crucifixion* to price the labour.

GENERAL.

The Vicar of St. Helen's, Bishop Auckland, has discovered, hidden by masonry in the chancel of the church, a fine example of a piscina, believed to date from the eleventh century.

The Trustees of the British Museum have presented to the Corporation of Glasgow, for the museums of the city, cases containing a series of about one hundred electrotypes of the principal medals illustrative of British history from the days of Henry VIII. down to the close of the Peninsular War and the career of Napoleon Bonaparte.

The Foundation-stone of the Fine Art Galleries, Glasgow, is to be laid to-day by the Duke of York.

The Excavations undertaken by the French School of Archæology at Delphi will be shortly resumed. The ancient gymnasium is selected as the site of the exploration.

An Exhibition of Shropshire antiquities is to be held in Shropshire next spring. Mr. H. Southam is the honorary secretary.

The New General Hospital, Birmingham, has been visited by the members of the Birmingham Royal Society of Artists, who have contributed a collection of works for the adornment of the walls.

Mr. F. A. Bather, of the department of geology in the British Museum, has been sent on an official mission to Russia to inspect and report upon the museums and scientific institutions in that country.

Lord Beauchamp has offered to present to the City Council of Worcester a pair of entrance gates to Pitchcroft, lately acquired as a public recreation ground.

The Dublin Corporation have increased the salary of Mr. Harty, the borough surveyor, to 1,000*l.* a year.

A Marble Tablet, erected in Kelloe Church in memory of Elizabeth Barrett Browning, was unveiled on Tuesday by Canon Kitching, of Durham. On the tablet is the following inscription:—“To commemorate the birth in this parish of Elizabeth Barrett Browning, who was born at Coxhoe Hall, March 6, 1806, and died at Florence, July 29, 1891. A great poetess, a noble woman, a devoted wife. Erected by public subscription, 1897.”

The Colne School Board have decided to erect a new technical school and public library on a site in Albert Road, the maximum cost to be 5,500*l.*, which, with the cost of land, viz. 1,300*l.*, would amount to 6,800*l.* Two prizes of 50*l.* and 35*l.* will be offered for the best designs.

The Architect.

THE WEEK.

LEEDS is well adapted for a Sanitary Congress. During some years past progress has been made, and the life of the citizens is of longer duration, but various arrangements connected with property prevent the Corporation from carrying out improvements as expeditiously as is desirable. Those who remember Leeds twenty-five years ago must be struck by the different appearance it presents to-day. The inky river is an eyesore, but with so many manufactories along the banks the purifying of it is no easy task, but the delay is favourable to the maturing of serviceable schemes of sanitation. In other cities and towns much money has been wasted by precipitate action, and from that loss Leeds will be spared. The Corporation are acting with much energy, and when we learn that three-quarters of a million are being expended on street improvements, it is evident that nobody can charge the Municipal Government with indifference. The scheme for dealing with the insanitary area is one of the most colossal that has been devised.

MR. WILLIAM MATHER, of the Salford Ironworks, may always be counted on to offer wise suggestions on strikes which affect his business. From his position, what he says should be considered with respect, for as a representative employer he is acquainted not merely with the conditions of his own order, but of the men also. MR. MATHER considers it is time the engineers' strike should come to an end, as already it has inflicted enough misery on men, women and children, who are outsiders. He therefore proposes:—

1. That the working week shall consist of forty-eight hours, with a mutual agreement as to shifts, overtime and other details to meet special circumstances.
2. That the question of the employment of machine tool and labour connected therewith, which has recently been the subject of discussion between the Employers' Federation and the Amalgamated Society of Engineers, and other questions not at present mutually agreed upon, shall be settled on such lines as the Employers' Federation shall be willing to accept.
3. That on a settlement being arrived at, the Employers' Federation undertake to do nothing for the purpose of impairing the trade union, that no member of the Amalgamated Society of Engineers shall be treated with less consideration and respect than he received before the dispute, and that no member of the Amalgamated Society of Engineers shall be subject to exclusion from or disqualification for employment in any works of the members of the Employers' Federation so long as the settlement exists. It will be seen that this proposal is intended to secure to each side what they most desire in exchange for what they regard as of less value in comparison therewith. Of course it is a compromise, but it would afford the basis of a lasting settlement.

THE Blue Book on the trade of the British Empire and foreign competition contains much which is suggestive. If it served no other object than to show how far foreigners are wresting the trade from Englishmen in the colonies, its appearance would be justified. The proportion of foreign to total importations sometimes rises to 80 per cent. In particular cases the foreigner now does more than 50 per cent. of a trade which a few years ago was admittedly British. In Hong Kong for wire, and in Malta for wrought-iron, the Belgians have practically ousted their British competitors. The countries which are most frequently mentioned in the returns as seriously competing with British goods are, without doubt, the United States and Germany; in some lines Belgium is an equally energetic competitor, but her scope appears to be more limited. In the East the competition of Japan is rapidly becoming the leading feature in the trade of that part of the Empire. German cement, for example, having a finer grain and lower price than what is made in England, has come into favour in various colonies. The lighter and cheaper furniture of Austria and the United States is superseding British productions. Owing to the effect of patents and advertising,

tools of industry and implements by Americans are preferred. The principal attraction in foreign goods is, however, their cheapness. The finish is also much greater, and in many cases the packing is superior. The general conclusions drawn from the returns are:—(1) In the best classes of goods and in the capacity to put the best possible article on a market which requires it the British manufacturer (and this seems generally to mean the manufacturer from the United Kingdom) is still supreme. (2) There are certain exceptions to the above rule, chiefly in the case of machinery and tools of certain patterns, and in favour of the United States. Yet in these particular lines the Canadian manufacturer is often a successful competitor with those of the United States. (3) A great portion of the general colonial market is not a market for the best class of goods, and in proportion as cheap and finished imitations of such goods can be put on the market the trade will go away to the producers of such imitations. This is precisely where the foreign manufacturer is coming in. (4) There is some danger that, where the trade goes to foreign competitors in the cheap goods just mentioned, a certain proportion of the better class of trade may also be diverted eventually.

It is not every enterprise in seats for the Jubilee crowds has been so successful as St. Clement Danes, in the Strand. The seats were certainly piled to a height which caused some alarm, but 5,750*l.* is an enormous sum to derive from the desire to witness a spectacle which was so brief in its duration. The money belongs to the rector, the Rev. S. PENNINGTON. He has generously withdrawn his claim on it, and the whole sum is to be devoted to the restoration of the church. There are many who would like to see the building removed, in order to allow of the carrying out of an improvement scheme for the Strand. But the associations with Dr. SAMUEL JOHNSON are still too strong to be annihilated, and it is not unlikely that the brass plate in his pew will soon be the only memorial of his connection with the Strand.

A PAPER was read on Wednesday at the Sanitary Congress, Leeds, by Dr. J. SPOTTISWOODE CAMERON, entitled "Drain-testing: Some facts revealed by testing the drains of 1,121 houses in which typhoid and diphtheritic disease was thought to be present." The value of the material gathered as the result of drain-testing in Leeds had, he said, been less than it might otherwise have been, owing to the possibly unintentional selection of those houses occupied by the poorer inhabitants of the city, and to the incompleteness of the methods of examination employed. It seemed to many of them that the day had gone by when the duties of a ward-inspector should be limited to the verification of nuisances complained of by the householder. If the sanitary service was to become an efficient preventive, they must examine the houses in their districts before, and not merely after, they had given rise to disease. From 1894 to the end of 1896 the sanitary department of Leeds had specially tested 1,121 houses in which typhoid and diphtheria were supposed to have occurred. Of the houses thus examined no fewer than 30 per cent. allowed the smell of the test placed in the drain or sewer to enter the dwelling. After giving the results of the examinations in detail, he said he thought the figures would warrant the following conclusions:—(1) As even in houses free from the special dangers due to the presence of a water-closet within the dwelling, and further protected by the disconnection of all other waste-pipes, drain-testing revealed serious defects in nearly 12 per cent. of those tested, it is obvious that there should be a regular systematic and periodical testing of all house drains. (2) This periodical examination by tests should be three times as frequent where, though free from the special dangers attending the inside closet, the other waste-pipes are not "cut off" outside the house. (3) It should also be three times as frequent where, though all other wastes are disconnected, there is a water-closet within or beneath the dwelling. (4) It should be six times as frequent where there is the double danger of an inside water-closet and undisconnected house wastes.

HISTORIC ORNAMENT.*

IT is said by Mr. WARD in the introductory chapter of the new treatise on decorative art that "we are handicapped in the development of anything new in the way of an architectural style by traditions of the past. Our knowledge of what has been done in the past, paradoxical as it may appear, has proved itself a great stumbling-block to the progress of new ideas." Although he holds that belief Mr. WARD, by the publication of his book on "Historic Ornament," is increasing the number of stumbling-blocks and doing his best to retard progress. It is a great pity writers on art will not have the courage to be honest. They must know that the work of the past is like a great treasure-house, which can be used without any restriction, and it is absurd while explaining the value of the contents to advise those who have come to carry off spoils against taking advantage of their privilege. So long as antiquity is treated with a reverence that often becomes folly, we must expect the ornamentists will take advantage of the general feeling, and instead of inventing forms will practise the less troublesome process of adapting them from ancient examples. When men and women are taught by writers like Mr. WARD "that the best period in the life of historic styles and its duration corresponds with that of the highest culture and religious thought of the people at their settled and most flourishing epochs," the natural conclusion is that it becomes a duty to keep up ancient patterns. He implies that Victorian Gothic failed from the absence of high culture and religious thought, but surely England was as richly endowed in qualities of the kind in the nineteenth as in the fourteenth century. There are so many restrictions now imposed that an inventive designer has as little chance of appreciation as an inventive judge. On the bench a man has to follow precedents regardless of their equity; he is only there, he will say, to administer the law as interpreted by predecessors. The respect shown for leading cases corresponds with the fidelity to "historic ornament" which teachers of design always display. It may be that we cannot emancipate ourselves from the forms which were devised by primitive designers, but so long as we are content to be indebted to them, it is absurd to show our gratitude by railing against them. If we are sincerely desirous of freedom and development let us begin by eschewing whatever is historic, and with the great stumbling-block out of our way we may hope to make progress.

The fact that four hundred and thirty-six illustrations are to be found in Mr. WARD's volume is by itself enough to suggest the hold which ancient forms have still on designers and the public. Many are taken from the South Kensington handbooks, still more from the excellent books by MM. PERROT and CHAPIEZ. But while we can find no fault with them as illustrations, it is not easy to discover on what principle they were selected. The text is written up to them, and it must be said that the quality of architecture and ornament bears little correspondence to the number of pages employed for the descriptions. Egyptian art, for example, is allotted sixty pages, while Greek, Lycian, Etruscan and Roman art are crushed into a similar space. Indian art, which is rich in historic ornament, has ten pages, Gothic has twenty, and Renaissance forty, or less than is devoted to Chaldean and Assyrian art. In modern times Renaissance examples are more freely utilised than those of an earlier period, and it would have been an advantage for the student to possess the information which he is likely to require. The book may, however, be intended for candidates who are ambitious to attain such honours as the Science and Art Department can confer, and with all who are infatuated in that way utility is not of much account.

The author says that "in the development of nearly all historic art we find that the religious aspirations of man were the chief factors. The forms of ornament were generally derived from the figurative signs of sacred animals, plants and other mystic symbols of a religious meaning, and were in the end converted into meaningless but æsthetic ornament. This is the history of nine-tenths of

historic ornament that has survived the decay of nations." Unfortunately the explanation is too true. Religious aspirations in our time, if expressed in ornament, would produce forms very different from those of antiquity. For in the old days religion was an auxiliary of government, and its main object was to excite terror. The severity which is found in Egyptian, Assyrian, Persian and earlier Greek work corresponded in spirit with the laws which were obeyed. It is possible that the human mind rebelled against the tyranny, and if we possessed examples of the stuffs which were used in clothing and other objects of an unimportant and fleeting character we might discover patterns which were not so geometrical and oppressive. Some of the objects found at Mycenæ indicate that heresies in ornament were not impossible. But as objects in stone and metals are those which have commonly survived, we are forced to take our notions of ancient art from them alone. The care taken is manifest, but when there is a continuous repetition of patterns executed with equal care the whole becomes more wearisome than a piece of machine-printed cotton. For in the latter there is generally some attempt to subdue the monotony by the simplicity of the pattern, but the ancient workers in stone and metal seemed to think they could not be too rigorous in representing geometrical forms. The objects in the Gold Room of the British Museum show the extent to which monotony prevailed in periods when the arts were supposed to flourish.

When ornament is employed as an accessory to architecture a severe character may generally be imparted to it. Work that has to be executed in hard stone, and which is expected to endure for a long period of time, can with advantage exhibit subservience to the conditions imposed on it. But if the floor of an Assyrian palace exhibits carving in low relief of rosettes, stars and lotus leaves, it does not follow that a British carpet should present a similar combination of forms. Yet that arrangement is not unknown. The more or less faithful reproduction is not to be excused by saying that the Assyrian carving must have been a copy of a carpet or piece of woven stuff. We may take our pleasures sadly, but there is not such a dearth of invention among us as to make it necessary to go back to a remote age for patterns for borders and the like. The school inspector in "Hard Times" laid down the laws of ornament according to one theory when he told the children that they must for all purposes employ combinations and modifications of mathematical figures which are susceptible of proof and demonstration, or otherwise there would be no taste; but the children were scared by the prospect of a world with that sort of adornment, and they were wiser than their teachers in allowing their feelings to control them.

The numerous illustrations give to Mr. WARD's book the character of a collection which is the more trustworthy because it does not appear to be gathered with a view to the proving of any theory. The pages demonstrate that in the progress of ornament the aim has been towards lightness instead of massiveness, and efforts were continually made to approach nearer to nature. The Greeks, for example, were not too proud to derive *motifs* from the countries to which they gained access, but in every case they endeavoured to remove the heaviness which characterised foreign forms. The Ionic capital is far more graceful than any of its relatives, and the very lightness of the volutes inspired a French architect with the idea that they were derived from the turning upwards of the ends of a flexible covering that was thrown over an altar. Forms somewhat similar would serve as roots for the evolution of the Ionic capital, but with as much probability it can be said that the original suggestion for the volutes was derived from the lotus plant. There is a large capital in the British Museum which shows the spiral as terminating in a big flower of the kind. When we find one exception to the conventional arrangement we may assume there were many others devised, and that natural forms were not altogether avoided by Greek architects. The Corinthian capital is less logical than the Doric or Ionic, but on that account it is a stronger indication of a desire for lightness and grace, which were obtainable only by coming closer to natural forms. The Romans wished to be sumptuous in their ornament as in other things, but what we still see

* *Historic Ornament: Treatise on Decorative Art and Architectural Ornament.* By James Ward. London: Chapman & Hall, Limited.

in Pompeii, as well as what existed in the Baths of Titus, from whence the decoration of the Loggie in the Vatican was derived, is more refined. In Pompeii the dimensions of rooms which are represented on the walls must have been inspired by some forerunners of the bamboo building of the Japanese. If the Loggie of the Vatican are correctly copied, it is not unlikely that the patterns or objects represented were brought together at the suggestion of children. But the most remarkable proof of the tendency of the period is to be found in the Roman catacombs. They belong to the Christians, a class whose lives were scarcely worth a pin's fee. It might be concluded that in so uncertain a condition of affairs they would have sombre ornament, of which there were many precedents, but these chapels and tombs are made by means of painted decoration to assume a festive appearance, and the frivolity has been a puzzle to inquirers. The Olympian beings that were most attractive to the Pagans of the time were introduced as types of biblical characters. The Christians probably considered it was easier to go with the current than to stem it, and their commissions to artists force us to conclude that the yoke of religion was supposed to be easy and the burden light. In most Roman work vegetation is introduced as subservient to some other objects; but when it was announced that a philosophy of Christian life was to be derived from the flowers of the field, plant forms assumed a new importance. In the *Orpheus* trees are represented not only in the central panel, but in those around, and a new era in art was commenced. Conventionalism again asserted itself in Saracenic art, but how different it is to the conventions of an earlier period. The Byzantine and Romanesque show a multiplicity of causes at work. There were many invasions, and the clumsy hands that could wield battle-axes were not adapted to carve or paint delicate ornament. According to Mr. RUSKIN, "to the Gothic workman the living foliage became a subject of intense affection, and he struggled to render all its characters with as much accuracy as was compatible with the laws of his design and the nature of his material, not unfrequently tempted in his enthusiasm to transgress the one and disguise the other." The various periods are marked by the relative amount of lightness and naturalness found in the foliage, and there can be no doubt that in many cases flowers and plants were copied directly from nature. The Renaissance was a period of liberty and men followed conventions or natural objects with equal pleasure. In all countries of Europe we find plant form produced with an elaborateness which is sometimes startling. Our own GRINLING GIBBONS entered into the spirit of the style, and his wood-carvings came nearer to nature than any of the paintings of the time.

ELECTRIC TRAMWAYS.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

THIS subject is now coming very much to the front, and the municipal engineer or surveyor has very often before him the question of mechanical traction, the improvement of the service, especially the question of increased speed and the reduction of the working expenses. It may, therefore, be of interest to review the positions of the various forms of traction at the present time. The systems at present in use are horse, cable, steam, gas and electric (third rail, conduit, accumulator and overhead trolley).

With regard to horse traction there is no doubt that the cost for the track is low and the cars inexpensive, but the cost of operating is certainly high. The speed attained is very low, consequently passengers are driven to use railways for even short journeys. There is no doubt that an average speed of 5 to 6 miles an hour is rarely exceeded in our suburbs. The limits of speed which are imposed by the horses and the heavy deterioration in the life of the animals are undoubtedly the chief causes of the inadequate service. Another point, and one which should be more considered in these days of civilisation, is the cruelty to the horses. There is no doubt that the conditions of running are too heavy for a horse. Starting heavily loaded cars on

a gradient, the frequent starting and stopping, and the large force required to put the heavy weights in motion, combined with the bad effect on the horses due to running on the stone setts continually, are responsible for the extremely short lives of tramway horses.

The sanitary aspect of the matter must also be considered, as it is of great importance. It becomes necessary, when the traffic is at all heavy, to consider whether a mechanical system of tramway working can be introduced with advantage.

In considering this step it is probable that a system which does not require any great alteration of the track will be favoured. The most general systems which comply with this are steam, gas or oil, and electric accumulators. These systems do not require any reconstruction of the track (if it has been well laid), and no permanent constructional works.

Steam Traction.—There is no doubt that steam traction is convenient, cheap and reliable. There is no one who will deny this point; but when this is said there is an end of the matter. The system has been extensively tried in England, but it is losing ground, owing no doubt to the very objectionable smoke, noise and the appearance of the engine. English people do not view with favour the spectacle of a locomotive in the streets, and do not like the soot, sulphur and noise of escaping steam. It may be that the great improvements in steam-propelled vehicles for the ordinary roads will result in a noiseless steam boiler and engine, which will be smokeless; but, until then, steam-propelled vehicles will never be popular.

Gas or Oil Traction.—This system has come into use a little lately in an experimental way, but very little has been done practically. The facts that gas can be obtained in any town, that it can be easily compressed, that it is efficient and inexpensive, make it a very promising subject for experiment. There is no doubt that the gas-driven car will prove a formidable rival for any of the other schemes as regards cost of maintenance. The same arguments apply to oil-engines, but with rather less force, as it has been found that the cost of running is rather higher with oil than with gas, and that the engines are not quite so reliable. The disadvantages against the use of oil or gas are also numerous. The exhaust gases are very disagreeable, and it is doubtful if the local authorities will allow it to be discharged into the streets; the motor must be always running, as it is difficult to start, and complicated gears will be required to start a heavy car on a gradient; the gas or oil-engines are very complicated and are extremely liable to get out of order, the engines cannot be reversed, lubrication is difficult and it is necessary to carry either an explosive gas or an inflammable oil, neither of which are likely to meet with popular approval.

Electric Accumulator Traction.—This system of traction is one which has very many advantages, among which are—(1) noiselessness, (2) ease of control, (3) absence of vibration, (4) cleanliness and good appearance. These advantages have marked it out as being one of the few systems which are suitable for large towns, where overhead wires, escaping steam, smoke or exhaust gas are impossibilities. The system is also very suitable in cases where the service is infrequent; it is, in fact, the ideal system of traction. A small engine and dynamo can be used continually for charging the accumulators, and working under these conditions electricity can be generated and stored at a cost unapproachable by oil, gas or steam, or in fact any other system, including the overhead electric system, where the conditions are different, a large plant being required, and expensive overhead work to transmit the electricity to the car.

In years past, however, the storage batteries have been a failure. The heavy starting current, combined with the effects of vibration, have made the life of the batteries very short, so short, in fact, as to prohibit their use. There are now, however, some accumulators which give better promise of success, and there are two places, at least, where some very encouraging results have been attained, viz. Chicago, and St. Denis, in France.

The subject of accumulator traction cannot be dismissed by reference to past failures, as the accumulator has been very much improved of late. The question of weight is, of course, against the accumulators at present, but there is no

doubt that very many advantages are to be gained by their use.

We have now mentioned the various systems which do not need any alteration in the track, and will proceed to the others before giving the details of the various systems in use.

The Cable System of tramways has before it a great future under certain circumstances. This system consists of a cable which is continually in motion in a conduit under the ground. The car is connected to the cable when required by means of a grip, actuated from the car. In this system all the cars move at the same maximum speed, viz. that of the cable, while those going down-hill help those going up-hill. It is evident that this system has a great advantage in all cases where a heavy incline has to be mounted, as there is no difficulty as to adhesion of wheels, &c., and no very excessive strains on machinery. The chief difficulties are with the slots in the road, stones sometimes being wedged in them, thus stopping the traffic, and also the impossibility of using the systems for very long runs. The conditions under which this system is undesirable are when there are many curves, and when, of course, the service is not frequent. The cost of altering the track is rather heavy; the pulleys over which the ropes run have to be lubricated, and the rope requires frequent inspection and repairs owing to the tearing action of the grip when starting the car. Two very successful cable tramways are in operation—one on Brixton Hill and another in Birmingham.

The Electric Systems.—These systems are the ones which attract most attention. We hear of schemes for electric traction in almost every town in the country, and there is no doubt that every borough engineer will have before him some scheme for electric traction within the next year or two. The electric traction systems which entail interference with the existing tracks, or the erection of poles, may be divided into three systems:—(a) The overhead trolley system, (b) the conduit system (underground trolley), (c) the closed conduit (surface rail or stud), (d) various new systems including electromagnetic traction.

a. *The Overhead Trolley System.*—In this system the energy is conveyed from a central station to the car by means of an overhead wire supported on poles or on wires spanning the street. Contact is made with the wire by means of a pulley working on a spring arm fixed to the car; this spring arm allows the wheel to be always in contact with the wire, as it takes up the variations in level of the wire. This arm is, in the case of the pulley, on a swivel, so that it may take into account side movements of the car. In another case the arm is not provided with a pulley, but is merely a horizontal bar on a spring arm, there being no swivel. The width of the bar is sufficient to take up the greatest amount of side play, it usually being the full width of the car.

In most cases there is only one wire, the return being by earth; in others there are two trolley wires, to avoid the earth return. In the single trolley system the current passes from the motor to the framework of the car, and thence to the rails. The result of this is that great care must be taken to see that the rails are connected together electrically as well as mechanically. This is more difficult than it would appear at first sight, owing to the difficulty of making a good electrical joint with iron, due to rusting. There have been numberless rail bonds invented; but as a rule they must be looked upon with suspicion, owing to the previously mentioned fact that iron will rust. The only perfect method is of course electric welding. By this process the rail becomes continuous, but troubles are likely to occur with expansion. There is, however, no doubt that electric welding would be good in England, owing to the small ranges of temperature compared with those in America. The sinking of the rails in the road and the side-pressure exerted by the stone setts prevent serious buckling due to expansion, and also reduces the range of temperature to practically that of the ground instead of that of the air. Another process of rail bonding is by means of casting the ends together, molten iron at a very high temperature being poured between them. This is hot enough to fuse the surfaces of the rails, thus making the metal continuous. There is, however, a liability to get a bad joint in this process, owing to the different and prob-

ably crystalline structure at the joint. However, both these processes are in use in America.

The effect of a bad joint in rail-bonding is to cause a difference of pressure between adjacent rails, and so increase the drop of pressure between the furthest point and the central station. The result of this is that the greater part of the current from the further end prefers to go through the earth, and incidentally most of it goes through any good conductors it may find on the way. These conductors are usually gas and water-pipes, and although there is no harm in the passage of current through these pipes, the current must leave them again to get back to the dynamo. The pipes are severely corroded at the points where the current leaves them, owing to the electrolytic action. There is no absolute remedy for this, except to make the drop of pressure on the return circuit so low that the resistance of the earth return is high compared with that of the rails. If this is the case very little current finds its way to the pipes and the electrolytic action is negligible. There are several advantages of the single trolley line over the double. At crossings there is very little difficulty with it; the expense is lower and the street looks less crowded with wires. This latter advantage is very great in England, where convenience is sacrificed to appearance to such a great extent.

(To be continued.)

THE ARTS AND CIVILISATION.

THE arts are the landmarks of civilisation. By their means we are instructed no less in the social progress than in the extent of refinement to which at various periods the most celebrated nations of the earth have arrived. Like the Nilometers of old, they inform us of the precise changes they have severally undergone, no less than of the different degrees of elevation to which, in the fluctuations of empires and states, they have attained. Long anterior to any written record found in the pages of the poet or historian, even to that volume which we all hold in veneration, nations existed who employed, though in a rudimentary form, the language of art—that “inestimable art” which has been properly described as one which “softens, refines and embellishes the intercourse of life.” The means which the graphic and plastic arts supplied were among the earliest employed by the nations of antiquity for the expression of their religious aspirations and the preservation of documentary or biographical details; these were recorded in characters and forms of objects with which they were familiar, subordinated to an imaginative treatment which was not the mere result of accident, but a studied reflection of their spiritual wants as well as of their social condition. Thus, when we should now be otherwise deficient in a knowledge of primitive history, or dependent for it on fragments of fabulous tradition or unauthenticated travel, the language of art, supplied by the sculptor’s chisel or the painted wall, fills up the blank and furnishes the information we require. The aspiring tendencies of the human mind first considered art in its spiritual essence rather than in its material nature. Devotional fervour in the earliest times, as in the Middle Ages, rose superior to the deficiencies of optical observation or the dexterities of manual skill. The end and object of art being to aid in the promulgation of religion—the highest and most deep-seated principle of which our nature is susceptible—the absence of other sources of knowledge, the peculiar condition of the major part of society and the power of ruling hierarchies, invested art with the privilege of communicating to masses of the human family intelligence which could not have been conveyed in any other manner. Although the living principle that animated these arts was manifested in systems in which our sympathies have no share, they may yet command our attention for having endured through lengthened periods and furnished for our contemplation some of the noblest exercises of man’s ingenuity. Art then as a mental exercise, and in its loftiest application, may well challenge our calm inquiry, no less than furnish reasons for the successes which it achieved, and this also explains why, when that aspiration ceased to afford an impulse and give a direction to the energies of its professors, it should have declined from a great and sanctified system of expression, from an elevating and expanding exercise of mind into a narrow and limited channel of material agency. At a time when there was a spirit abroad which rose superior to material forms the artist looked beyond and out of himself into spiritualisms, and dealt in abstractions congenial with the feelings and the poetry of his own times; if he did not fully recognise art in its imitative capacity it was in consequence of respect for creeds, no less than of the short

comings which a defective education may have induced, and when afterwards he did employ natural objects with more strict regard to their artistic presentment, he did so by availing himself of their highest and completest forms.

ARTS AND CRAFTS IN GENEVA.

IN *La Tribune de Genève* a communication appears from Mr. Lawrence Harvey, who may be considered as the pioneer of technical education as adopted in this country by the County Council of London and other public bodies. The object of it is to demonstrate the superiority of Geneva as a training school for the architects of the future. "There is a position to be gained," says Mr. Harvey, "and Geneva is especially adapted to seize it, for neither in Zurich nor in Paris nor elsewhere can they form young architects that will satisfy the requirements of the public. The arrangements that are adopted now appear as if intended to compel students to acquire what is superfluous, and to forget what is indispensable for their future career. Is it a piece of strategy devised by old architects to defend themselves against the competition of young rivals, or is it stupidity? I cannot tell, but it is certain that in the practice of architecture one is always talking about money, and it is never mentioned in training schools or academies of art. This is the more strange if we consider what an architect is. He is a man to whose care large sums of money are entrusted in order that profit may be derived from them. As respects buildings for investment, that is a truth which all admit. An architect who does not know how to arrange building for investment wastes his client's money. The building may never attract a tenant, or the rent given for it may be insignificant; if the house must be sold the proprietor is sure to lose a part of his capital. But the facts are not less convincing when they relate to a country house or to a monument of any kind. The only difference is that the equivalent of the capital may be reckoned in services that are rendered or in satisfaction that is given. Is there, for example, one individual in Geneva who is not assured that the money devoted to the erection of the Brunswick monument is wasted? With an equal sum it would have been possible to raise a memorial which would have contributed to the reputation of Geneva as an artistic centre, whilst the existing monument is enough to raise a blush with all who look upon it. Still more, when he has to deal with an edifice of a purely decorative and ideal kind the architect is compelled to keep his eye fixed on the problem put before him, that is, to make the most of a sum of money by converting it into a constructive work.

"In order that he may profitably invest the capital of his clients, what has the architect to do? He must, in the first place, realise to himself the exact sum which a structure according to his plans will cost. In the case of ordinary constructions, buildings for investment or for pleasure, there are data which can be employed, and with which every builder is acquainted. But when the estimate relates to some simple work, such as an opening in a wall, the construction of a door or a partition or a roof, it is necessary to analyse the elements of the problem, and to consider, first, the cost of materials and, secondly, the cost of labour. In order to make the valuation correct it is absolutely necessary for a man to have had experience as a workman, to be familiar with the stone-cutter's chisel, the carpenter's saw and plane, and the hammer and tongs of the metal-worker. It will be asked, Do I recommend a seven years' apprenticeship in order to devise a few miserable details? That is surely too much to expect from architects. Insignificant details may appear, but in nine cases out of ten it will be found that at the commencement of an architect's practice it is with such things he will have to deal, and by means of them will succeed in gathering a *clientèle*. For where is the client to be found who is ready to entrust capital of a large amount to a young architect that he knows to be wanting in experience?

"But that is not all. In order to give assurance to his clients that they will receive value for their money, the architect must be thoroughly acquainted with the quality of the materials and the labour to which they are subjected. For that purpose a workman's education can render the greatest service to an architect. It is only in handling materials that one arrives at a knowledge of their properties. It is by operating on them that one discovers how work is to be done on them and what length of time is needed. It is, moreover, in the course of his apprenticeship as a workman that the architect will discover the tricks of trade, the frauds against which he must be on his guard at a later time in order to protect the interests of his clients. But what about art? How does it count in such an architectural education? Is there not a danger that it would cease to be reckoned among the fine arts? The fact is, however, that there is no surer way of becoming a true artist than by commencing with a practical study of the crafts. I could

investigate at any length the æsthetics of building, and there would be no difficulty in proving that the power of composition is in direct proportion to the possession by the architect of all the elements which should unite in his work; that good taste depends in a great measure on the exact adaptation of the form to the material and to process which it must undergo at the hands of the workman. As evidence I need only refer to the nave of the cathedral of Geneva. There is to be seen the work of men who have followed the career of an operative of men who, prior to the time when they were entrusted with erection of edifices, were stone-cutters or carpenters. In all Geneva there is nothing to be found more beautiful than the interior of St. Peter's. We may run through Europe on all sides, and we shall learn that during long centuries architects as workmen have raised buildings which are more and more marvellous in their execution, for architecture was then a living art which displayed increasing progress. Then a time arrived when all of a sudden the creative art was abandoned, and for it was substituted the copying of ancient buildings that had been forgotten and were misunderstood. There was an end to progress; there was no longer the breath of life; the ideal vanished, for the architects became archaeologists or painters or sculptors, and finally were transformed into gentlemen in black frock-coats, who were above handling a tool.

"Owing to its *Ecole des Métiers*, Geneva can now take up the broken threads and enrich the world with architects resembling those who constructed the cathedral of Geneva and the cathedral of Paris. It is not my intention to recommend young men to give themselves up to handicrafts in order that they may become practical. On the contrary, I consider that it is most desirable for architects to possess high culture, and it is for them above all that the study of the classics is advantageous. But I would say to those young folk who have already attained the power to appreciate Homer and Horace, that it would be well if they put on one side every sentiment of pride, and began their technical training for architecture by spending two years in the *Ecole de Métiers* in Geneva. If they will apply themselves to the task of learning all that can be taught to them, they will come out of the school competent to find employment as stone-cutters, carpenters, joiners, or metal-workers. The time spent in the school will have for its result a manifest superiority over rivals who have neglected similar advantages, and this will be seen in following out studies at a later time and in the struggle to make a name."

REPRESENTATION AND DESCRIPTION.

THE general nature of the formative arts as distinguished from language or description, from which their subjects are often taken, is too familiar to require much comment. It may suffice to advert to those principles of representation which have been derived from such a comparison, and which affect the question proposed.

In a subject taken from description it is required that the impression conveyed should be as nearly as possible equivalent to that of the written narrative; and this translation (for such it is) can rarely be accomplished without some deviation from the letter of the original in order to render its true meaning. It follows that where it is absolutely impossible for painting, which represents what passes in a single moment and in one view, to convey an impression equivalent to a given description, that description cannot be said to furnish a good subject for representation.

Sir Joshua Reynolds gives an instance of an ill-adapted subject of this kind which was recommended to a painter. "It was what passed between James II. and the old Earl of Bedford in the council which was held just before the Revolution. This is a very striking piece of history, but so far from being a proper subject that it unluckily possesses no one requisite necessary for a picture; it has a retrospect to other circumstances of history of a very complicated nature; it marks no general or intelligible action or passion," &c. The following appears to be the incident referred to:—"As soon as James entered the city he summoned an assembly of the peers to ask their advice and to make an apology to them for not having called a Parliament. In passing to the council he met with a shock, perhaps as severe as any he had felt. Meeting the father of the unfortunate Lord Russell, the old Earl of Bedford who had offered 100,000*l.* for his son's life, but which the king when Duke of York, had prevailed with his brother to refuse, he said to the earl, 'My lord, you are a good man; you have much interest with the peers; you can do me service with them to day?' 'I once had a son,' answered the earl sighing, 'who could have served your Majesty upon this occasion.' James was struck motionless."

The question here is not whether a good picture could be made out of two persons in conversation, but whether the precise story could be told. It is evident that it could not, and that the representation could not be equivalent to the description.

Among the changes which a subject may undergo in being transferred from description to representation may be mentioned the omission of circumstances which, however forcible and satisfactory in words, would be disagreeable when presented to the sight. One well-known instance may suffice. In the "Æneid" the serpent coils itself twice round the neck of Laocoon. Suppose some Mæcenas, more conversant in poetry than in art, were to employ a sculptor or painter to copy this description literally, the admirable lines of Virgil thus rendered would produce a tasteless work of art.

Not only forms, but colours, however agreeable in description, might be unpleasant to the sight, and the assumption that poetical allusions of this kind may be literally adopted in pictures has sometimes led to false criticism. In this respect the means of the two arts differ widely. An image is more distinct for the mind when it is compared with something that resembles it. An object is more distinct for the eye when it is compared with something that differs from it. Similarity is the auxiliary in the one case, contrast in the other. The poet succeeds best in conveying the impression of external things by the aid of analogous rather than of opposite qualities; so far from losing their effect by this means the images gain in distinctness. Comparisons that are utterly false and groundless never strike us as such if the end is accomplished of placing the thing described more vividly before the imagination, or of conveying an impression of excellence. In the common language of laudatory description the colour of flesh is "like snow mixed with vermilion;" these are the words of Aretino in speaking of a figure of St. John, by Titian. Numerous instances of the kind might be quoted from poets; even a contrast can only be strongly conveyed in description by another contrast that resembles it.

On the other hand, whenever poets have attempted the painter's method of direct contrast the image has failed to be striking, for the mind's eye cannot see the relation between two colours, to say nothing of the vagueness of their names. It has been already observed that words, necessarily presented in succession, are, strictly speaking, inadequate to the expression of harmony, the elements of which must be simultaneous.

Poets to avoid competition with the painter's elements, or rather to attain their end more completely, have often judiciously taken refuge in moral qualities when describing forms and colours. By means of such associations hues which would be far from agreeable to the eye become pleasing. All light, positive colours—light green, light purple, white—may be thus recommended to the mind's eye; no degree of dazzling splendour is offensive and no repose is required.

To insist, therefore, that a work of art should be absolutely faithful to the description from which it is taken (though that description might be excellent in itself, and true to the conditions of eloquent language) might be sometimes fatal to its success.

The restriction of representation to a single moment and a limited space has suggested various liberties in painting and sculpture, in order to render the impression as nearly as possible equivalent to that of the story represented. For example, in Raphael's celebrated painting representing the possessed boy brought to the Apostles while Christ was transfigured on Mount Tabor, the painter has taken the liberty of bringing the figures of the Redeemer and those who were with Him on the Mount during His Transfiguration near, and has reduced the mountain to a hillock.

This is an instance of a great liberty taken with space, but not with time, since the two events represented may be supposed to have happened together, and it is evident that in order to be equivalent to the description the scene of the Transfiguration required to be prominent. The ultimate object of the artist in proposing such a subject to himself it is not necessary here to inquire into.

The liberties taken with time are much more common, but they are only considered excusable in historic art when they greatly increase the force of the impression, and render it on the whole a more intelligible translation of the description. It is to be observed that the great artist above mentioned in most of his Scripture subjects does not depart in this respect from the letter of sacred history.

The liberties taken with the personal appearance of historical characters are thus defended by Reynolds:—"How much the great style exacts from its professors to conceive and represent their subjects in a poetical manner not confined to mere matter of fact may be seen in the cartoons. In all the pictures in which the painter has represented the Apostles he has drawn them with great nobleness; he has given them as much dignity as the human figure is capable of receiving; yet we are expressly told in Scripture that they had no such respectable appearance, and of St. Paul, in particular, we are told by himself that his bodily presence was mean. A painter must compensate the natural deficiencies of his art. He cannot, like the poet or historian, expatiate and impress the mind with great veneration for the character of the hero or saint he represents, though he lets us know at the same time that the saint was deformed, or the hero lame. The painter has

no other means of giving an idea of the dignity of the mind but by that external appearance which grandeur of thought does generally, though not always, impress on the countenance; and by that correspondence of figure to sentiment and situation which all men wish but cannot command. The painter ought to give all that he possibly can, since there are so many circumstances of true greatness that he cannot give at all. He cannot make his hero talk like a great man; he must make him look like one."

The precept here given, in its application to historical painting, properly so called, may require to be received with caution; and the great authority referred to by Reynolds may be quoted on the other side as having attained the grandeur of his style, at least without losing himself in vapid generalisation, a defect so frequent in the later Italian schools. The rule is chiefly applicable to works of large dimensions, and requiring to be seen at some distance; but in paintings which admit of nearer view, the power of expression has often triumphed over unpleasing forms.

The liberties taken with costume are notorious, and are frequent among the great masters. Their sole object seems to have been to be true to the imagination. Even in the instance of Nicholas Poussin—the most remarkable of the older painters for attention to costume—the air of remote antiquity, the classic probability which he contrives to give to his works, are addressed quite as much to the imagination as to the erudition of the spectator; and the artist's materials are selected or modified according to their applicability to this larger purpose, for he is frequently incorrect in the mere scholarship of costume. The rage for classic research in some modern (now nearly extinct) continental schools often led to the reverse of this principle, viz. the habit of addressing the understanding rather than the imagination. The weapons of Homer's warriors were chiefly tempered copper, not steel; but as few persons are accustomed to associate this circumstance with their conception of Homeric battles, the representation (for such representations have appeared) was unsatisfactory though true.

The extent of modern antiquarian researches in increasing information in archæology has increased the number of critics; and to be true even to the imagination now, a painter requires to be more attentive to the details in question than the earlier artists were. But the character of art is unchangeable, and the materials of costume are still to be considered subservient to the end of representation. Notwithstanding the gross errors in costume, which are observable in the pictures of the Venetian and Flemish masters, it will be remembered that such errors have scarcely weighed in the balance when their merit as artists has been considered; and that, on the other hand, the most rigid correctness in costume would never of itself be sufficient to constitute a fine picture.

The practice of the great Italian painters resembled that of the artists of antiquity. Their first care was to avoid as much as possible a modern appearance and ordinary associations in dress; and this was frequently extended even to contemporary subjects and portraits. In selecting obsolete costumes they were at least sure that taste could not alter respecting them, or that if any reaction took place it would be in favour of such costumes. The dress being once removed from the immediate present they were not particular about the precise period of a subject, and were guided chiefly by the demands of the art. Thus Giorgione appears to have dressed his figures in costumes older than those of the period in which he lived. Raphael, who willingly introduced the flowing robes of the clergy and religious orders (unaltered from much earlier times) and the armour and habiliments of Swiss guards (uncommon from their foreign appearance), took great liberties with the general costume of the period in which he lived.

Many of the licences above adverted to are regulated by the style of the art; different subjects, indeed, suppose different modes of imitation, and even different dimensions. The imitation of the details of dress is one of the points which characterise works of art of moderate size; for the fullest means of imitation which painting can employ are, strictly speaking, most appreciable in such dimensions, as coming within the range of most distinct vision, and hence the more complete those means the more the introduction of accidental circumstances is compatible with due gradation. But, as dimensions and distance increase, or as the scale of effect which represents the differences of nature, from whatever cause, becomes less full or less appreciable, the objects represented require to be selected with an especial regard to their importance, beauty and character.

Turner's House at Twickenham, known as Sandycombe Lodge, Sandycombe Road, St. Margaret's, will be offered for sale on September 21. According to Mr. Ruskin, the artist bought this house in 1808 and resided there till 1827; but other writers place the period of his residence at Sandycombe Lodge as from 1814 to 1826. The auctioneers state that the house was built after designs by Turner himself. The original structure has been added to,

"PROVAN'S LORDSHIP," GLASGOW.

IN the discussion about the house in Glasgow which has a claim to be considered the oldest, "Provan's Lordship" is to the fore. The following remarks on the building by Mr. P. Macgregor Chalmers, architect, appears in the *Glasgow Herald*:—

The old house which stands fronting Cathedral Square, at the corner of Macleod Street, has been attracting public attention recently. The following note is written after an examination of the building. My experience is that M'Ure, the first of Glasgow's historians, is not to be tampered with lightly. This short study adds another "stone to his cairn." Referring to this house, he wrote:—"The prebendary of Balernock, or, as he was called, the Lord of Provan, and his rectory, was always designed the Lordship of Provan. I am really at a loss to know the import of this designation. His manse was at the large house near the Stable Green Port, that now belongs to Mr. Bryson, of Neilsland." It is worthy of note that it is not stated that the manse was this large house. Referring to the thirty-two manses which Bishop Cameron is credited with having ordered to be built, it is mentioned that some were "now demolish'd and level'd with the ground," and in a general reference it is said that the manses "were so changed and gone through so many hands that the memory of many of them are quite forgotten." It would appear that the only fair interpretation to put upon M'Ure's statement is that the manse of Provan had stood on the site of the large house near the Stable Green Port. It has been shown recently that the present existing house was in the possession of Mr. Bryson, of Neilsland, when M'Ure wrote. As the title "Lord of Provan"—a title enjoyed by King James IV.—did not cease at the Reformation, it will be interesting if it can be demonstrated that the existing house standing on the site of the ancient but demolished manse retained the title of "Provan's Lordship."

The present building is of two dates. The earlier and much the larger portion is a long, narrow oblong, about 18 feet wide within the walls, extending along the front to Cathedral Square, with a small projecting wing on the west at the south end. The walls are nearly 3 feet thick. The joists of the floor are of oak, or other hard wood, about 6 inches square, and they run the long way of the building. The roof also is of oak, and the old slates were fastened to the sarking by long oak pegs. Many fragments of the old stone ridge are still preserved. The windows and doors have no ornament save a simple small chamfer. Several of the windows have well-executed stone seats on each side. The fireplaces, which are of more than ordinary size, are of one design, with chamfered jambs carrying moulded corbels on which the lintels rest. I found traces of a fireplace of similar design in one of the ground-floor shops, and at a level which shows that the original floor was considerably lower than at present. Having secured the use of a long ladder I climbed up to the roof, and there on the south-western corner, on the corbel of the gable top, I found the date 1570. There was the appearance of a rough projection high up on the south wall, and this, I was assured, was a sundial. Unfortunately, the whole wall is used as a hoarding for posters, but with a brush and water, and a liberal use of my fingers, I soon had the stone laid bare and cleaned. I found half a sundial only. The other half was probably removed recently and needlessly when the present rain-water pipe was put up. The portion remaining, however, is valuable. It bears the following:—

W. PROVA

8

9

IO II I2

There are also a few radiating hour lines. The inscription, when complete, probably read, "W. Provan's Lordship. B." It is an interesting fact that on December 6, 1570, Thomas Baillie transferred the lands of Provan to his brother, William Baillie, senator and president of the College of Justice, by the title of Lord Provan. He died May 26, 1593. Provan passed to the Hamiltons of Silvertownhill, and later, on March 3, 1669, was purchased by the town of Glasgow. It is probable that it was at this date that the small addition was made to the house on the west, to the north of the existing west wing. Possibly the character of the house was considerably changed. It was at this period that two of the original large fireplaces were greatly reduced in size by the insertion of new jambs within the old. The mouldings used are of the same date as those on the entrance doorway which was made in the new addition. That this north wing is a later addition is made abundantly manifest at the roof. The old roof, with its spars and sarking, resting on the original back wall, was retained and still exists. All that was done was to remove the slates. The new roof, which is of a flatter slope, was laid over the old one.

This old house possesses many features of considerable interest and it is well worthy of preservation as a relic of old Glasgow. The personal interest attaching to it is now seen to be for lawyers rather than for churchmen. M'Ure's statement

as to the site of the manse of Provan may now be accepted. I have been greatly indebted to Mr. Innes, the caretaker of the property, for his kindness in allowing me to examine all parts of the building and for his assistance.

ATMOSPHERE IN CITY CHURCHES.

A CORRESPONDENT of the *Guardian* says:—As a rule, there is never any thorough ventilation at all. The system of having two or even three absolutely dark lobbies between the church and the open air, each closing with a spring door, makes any ventilation very difficult. Too often, in a few minutes, after several hundreds of people have left, every door is closed and locked, until a short time before the next service begins. Then, again, in by far the greater number of our churches, the daylight is so rigorously shut out that an enormous amount of gas has to be burnt, thus adding very greatly to the heavy and poisonous state of the air. Why are our churches dark? We worship the light, we call ourselves children of the light, and yet as one enters one after another of these otherwise beautiful buildings, the one text that comes first to mind is, "Ye love darkness rather than light," &c. Is the God-given light of the sun an evil thing, that we should shut it out so persistently? If only we would let the sunlight into our churches, in too many instances we should at once start with horror to see how dirty they are. It cannot but be so while we shut up the breath-laden, gas-laden air, to settle upon walls and carvings and upon costly ornamentation, until it forms a foul crust on everything. In many modern churches there is an elaborate system of roof ventilation, of which the architect is justly proud; but in many it is too elaborate to be of practical use. All the winter, when double the gas is burnt, these ventilators in so many churches are never opened at all. Roof ventilators, to be of real use, should be easily manipulated by cords and pulleys, and it should be the churchwardens' duty to see that all these are opened immediately after every crowded service for at least twenty minutes, even in cold weather. If, at the same time, the large doors of the church on two or three sides of the building were also wide open, all the vitiated air would quickly disperse; a new supply takes its place, and then doors and ventilators in winter can be shut and the church made comfortable for the next service. The average verger's idea of ventilation is to open a window about an inch during the service. These windows are generally just the height of one's head, and the cold air rushes in like a sharp knife, giving stiff necks and neuralgia with a liberal hand, yet practically doing nothing to freshen the depressing heat-laden air. How much harm is done by the fearfully poisonous air of so very many of our churches it is impossible to define. We know that many of the clergy fall ill; even the strongest are altogether exhausted after every Sunday, and this exhaustion is the direct result of foul air. We know that many business men refuse to come because of the weariness that ensues. Thousands are deterred every Sunday from coming because of it, and large numbers of those who do come find the intense heat, the heavy air a very grievous preventive of true devotion. The mind cannot give all its powers of attention when the body is required to suffer so painfully. Until our churches are full of sweet, pure sunlight, coming down in rich abundance from clerestory windows that will open freely, and giving us the light from above; until the air is as sweet and pure as in our own drawing-rooms and we have swept away the forbidding spring doors that so certainly deter the entrance of the stranger; not till then can we hope to get the intelligent artisan to come to church, and not till then can we hope to find the worship of our churches a true service of praise and rest and undisturbed devotion. Why cannot this form a subject for discussion at one of our Church Congresses?

EDINBURGH BUILDINGS.

THE President of the Dundee Institute of Architecture has invited the members of the Edinburgh Architectural Association to accompany the members of the Institute on their visit to the M'Ewan Hall, Blackford Observatory, &c., which will take place to-morrow, Saturday. Among the places to be visited are M'Ewan Hall, adjoining the University Medical College; Blackford Observatory; Craigmillar Castle, where Mr. Thomas Ross, architect, Edinburgh, who will accompany the party, will describe this ancient fortified mansion, whose outer wall bears the date 1427. In 1479 John, Earl of Mar, was imprisoned here, and, tradition says, put to death by the opening of his veins in a bath for alleged conspiracy against his brother, James III. The castle was frequently the residence of James V., and the chief country retreat of Queen Mary Holyrood will be next visited. After luncheon the members of the party may individually visit the Castle, St. Giles's Cathedral, National Gallery or Museum of Science and Art.

NOTES AND COMMENTS.

Now that Herr PÜLSZKY, the director of the National Gallery of Buda Pesth, has passed away, a great many stories are current about his weakness in giving big prices for works of art which were nearly valueless. He directed one of his representatives to go as far as 125,000 francs for a portrait of an unknown man by SEBASTIAN DEL PIOMBO. He placed it in a prominent position in a gallery, but the next day it was put out of sight. It is hard for a director of a gallery to be always infallible; precious works mysteriously turn up from time to time, and the officials who do not secure them are blamed for their indecision. There are comparatively few works by SEBASTIAN DEL PIOMBO, and, although MICHEL ANGELO chided him for his sloth, he could hardly help painting a larger number of pictures than those bearing his name. An amateur who devoted himself to a search of the artist's works could hardly fail to make some interesting discoveries.

THE continuous purchase of works of art by the French Government, and which disappear as soon as they leave the exhibition, necessarily leads to various accumulations. From time to time we read of discoveries in out-of-the-way places. One of the latest was in an old stable, which is about to be cleared away for the purpose of enlarging a shop. Among the collection is a fine portrait in his coronation robes of NAPOLEON I., by RAMEY. In this the Emperor's countenance assumes an expression of majesty which was not surpassed by any of the Court sculptors, while the details of the robes have the delicacy of porcelain. Another work by the same sculptor represents LOUIS PHILIPPE, surrounded by his sons, receiving the charter of 1830 and the oath of the army. There are also figures and busts of NAPOLEON III. and the Empress EUGÉNIE. There is also a recumbent figure of the Duc D'ORLÉANS, who is draped in a mantle of St. LOUIS. After lying neglected for so long a time, the sculpture is to be sent to Versailles, that refuge for the waifs and strays of art.

ALTHOUGH valuable prizes may be founded it is not always easy to bestow them. The will of NOBEL, the inventor of dynamite, seems to be up to the present a dead letter. He founded four prizes of 10,000*l.* each, which were to be annually awarded to men who deserved them by their labours in science, letters or philanthropy. The heirs of the chemist are attacking the arrangements, and not one of the four societies who are to choose the recipients has received the money for last year's prizes. Another prize of his was to be given to the man who had endeavoured most efficaciously to render war more impossible. That prize is to be awarded by the National Assembly of Norway, and a commission has been appointed to investigate the claims of the competitors. No more than two competitors have as yet appeared—one is the painter VERESCHAGIN, the other Count TOLSTOI. M. VERESCHAGIN's pictures of Russian battlefields were exhibited some years ago in Bond Street, and the pride, pomp and circumstance of glorious war appeared more brutal than any scenes in an abattoir. It was courageous of the painter to oppose national opinion in Russia, and he undoubtedly has a claim on the 10,000*l.*

THE goldsmith's trade in Paris is probably the most important of all. The influence of the costly and beautiful examples in the precious metals extends to the humblest *objet de Paris*, and examples of jewellery which only cost a few sous have a character which is not rivalled by goods at a higher price in other countries. The death of LUCIEN FALIZE at the age of fifty-eight is therefore a more grievous loss to France than would be caused by a dozen deputies. He was recognised as a distinguished artist, and his productions were sought after in all the courts of Europe. M. FALIZE was the successor of M. BAPST, the jeweller to the crown, and his ambition was to uphold the reputation which for centuries belonged to French metal-work. Among his later works were the toilet service in massive silver which was presented to the Princess LOETIZIA on the occasion of her marriage with the Duc D'AOSTA, the *Gallia*, which was the most important example of its style in the Exhibi-

tion of 1889, and the golden olive-branch which M. FAURE deposited on the tomb of ALEXANDER III. Let us hope he will be succeeded by some other artist who will carry on the old traditions which have made Paris [supreme in jewellery.]

THE psychical visitations of which we hear in England suggest that the spirits are wanting in originality; apparently all they can do is to make a noise. A story has been revived in Paris which reveals that spiritual manifestations, as other things, are better managed in France than with us. The witness and recorder was THOMAS COUTURE, whose *Roman Orgie*, now in the Louvre, is one of the great pictures of the century. The artist never gained the success which was the right of a man of such genius, and in consequence he became cynical and looked at everything in the most unimaginative way; he was therefore entitled to credit when he testified to a phenomenon. COUTURE was employed on the wall paintings of the lady chapel of the fine church of St. Eustache. From time to time he was disturbed by the appearance of a harlequin of the old school, who gracefully saluted and pirouetted round the chapel. Sometimes he would express his gratitude by delight at the painter's work. The harlequin even ascended to the scaffolding and carefully examined the ornament of the cornice. The first time COUTURE saw him he imagined that harlequin was one of the street pantomimists of Paris who had found his way from the Halles into the chapel, but when the painter examined the door leading to his enclosure he found it was double locked. The visits continued for about a week, and COUTURE was eager to utilise his admirer for a pantomime scene, but he disappeared. Subsequently he came across an old book entitled "Life of DOMINIQUE, the Celebrated Harlequin of the Italian Comedy." There he discovered that the actor was greatly admired by LOUIS XIV. He made some money, and on his death he bequeathed the greater part of it for the upholding of St. Eustache, on the condition that he was allowed to be buried in the lady chapel. It was DOMINIQUE who gave the famous answer to the king. His Majesty had been dining, and, pointing to a golden dish, said to an attendant, "Give this dish to DOMINIQUE," who replied, "Shall I have the partridges also, sire?" The event may be no more than hallucination, but in the haunted houses of which we hear so much in this country it is a pity our spirits are not capable of such dramatic and charming incidents.

MR. B. T. BATSFORD's forthcoming publications include "Later Renaissance Architecture in England," by JOHN BELCHER and M. E. MACARTNEY, the second and concluding part; "Bungalows and Country Residences," by R. A. BRIGGS, fourth edition, with additional plates; "A History of Architecture for the Student, Craftsman and Amateur," by Professor BANISTER FLETCHER and BANISTER F. FLETCHER, third edition, revised; "The Influence of Materials on Architecture," by BANISTER F. FLETCHER; "Modern Opera Houses and Theatres," by E. O. SACHS, third and concluding volume; "Examples of Old Furniture, English and Foreign," drawn by A. E. CHANCELLOR; "Windows: A Book about Stained and Painted Glass," by LEWIS F. DAY; "Alphabets, Old and New," selected by LEWIS F. DAY; "Examples of Greek and Pompeian Decorative Work," measured and drawn by J. CROMAR WATT; "Estimating," a method of pricing builders' quantities for competitive work, by GEORGE STEPHENSON, third edition, revised; "Repairs," how to measure and value them, by GEORGE STEPHENSON, second edition, revised.

THE SANITARY CONGRESS.

THE presidential address at the Congress of the Sanitary Institute now open at Leeds was delivered in the chemistry classroom of the Yorkshire College by Dr. Robert Farquharson, M.P. He said the responsibility of an introductory orator on such an occasion as this is much increased by the fact that hygiene has now become fashionable, and that most people nowadays know at all events the elementary principles on which it works. "All great subjects like this, and more especially those which involve some dislocation of antiquarian superstition and domestic prejudice, must pass through a variety of stages. Next, when the general public recognise that we are in dead earnest and have come to stay, the stage of active opposition sets in; and, looking backwards, we can hardly wonder at the slow movement of people's minds in favour of sanitary progress. Poets and novelists have cast a halo of chivalry and romance around conditions of dirt and discomfort which must have made the lives even of knights and barons barely worth living two centuries ago. Old prejudices die hard, and old-fashioned people do not like being disturbed in their belief in the old order of things handed down to them by their forefathers. But we have nearly outlived all this; ventilators are no longer stuffed up; the working classes, no less than their employers, are beginning to be connoisseurs in the quality of their atmospheric conditions, enjoy a good wash as much as a University graduate, and are fully prepared to appreciate the advantages of hygienic house accommodation at other people's expense, and so we have reached the stage of enthusiastic acceptance and universal approval, and the sanitary reformer is as much petted and caressed as he was formerly scouted and despised. No properly instructed person in these enlightened days would dream of taking a house without a thorough inspection of and report on its sanitary arrangements; water analysis and food analysis keep us fairly free from adulteration, and most of us know pretty well, or at all events know, how to get the information as to the amount of help given us by the law in keeping our health fairly sound.

Man a Good Animal.

We must come to the conclusion, reluctantly, perhaps, but inevitably, that the race is to the swift and the battle to the strong, and that unless we are well equipped physically for the contest we are outpaced and shoved aside, and laid on the shelf along with the other failures of the world. The well-worn quotation from Herbert Spencer sums up the whole case:—"The first requisite of life is to be a good animal, and to be a nation of good animals is the first condition of national prosperity." The good animal forces his way to the front by the sheer force of pushful progression, and it is our duty, both to ourselves and others, to see, so far as we can, that our vital functions are maintained in good repair. Each one of us has, or ought to have, our own place and our own work, which we fill or do, and the filling or doing of which according to our highest capacity should be the supreme aim of our lives and of others, because the sum of the success and progress of our country is made up of the vigour and intellect of the individuals which compose it. Each one of us has a right to expect that his neighbour will not only contribute his fair share to the efficient working of the universe, but that he will not hinder or obstruct others who are trying to do the same.

Modern Labour and its Reward.

I wish to make a couple of protests. The first is against the monotony of modern labour, caused partly, no doubt, by the rapid extension of labour-saving machinery, but also largely due to what Dr. Beddal, in his very suggestive "Address on Health" (Social Science Congress in Edinburgh, 1880) called the specialisation and minute subdivision of employments. "The influence of this last alternative," he continues, "on the health of the workman has never been thoroughly worked out. If not counteracted by some extent of general education, or opportunity for employment of leisure, it must apparently tend to dwarf both body and mind by the unbroken monotony of action." There is food for reflection in this, and I recommend it to your mental appetite and digestion. Protest number two is against the doctrine, for which I think the Bible is primarily responsible, which was further elaborated by Ruskin, and which is now, I understand, accepted by certain sections of labourists. And that is that the workman should be paid the same wage, whether he works well or ill, whether he be clever or stupid, skilful or clumsy, industrious or lazy. I must not enlarge on the moral or social side of this dogma of some trade unionists, but I am entitled to say that, in my opinion, it is hopelessly at variance with the common-sense laws of health, and therefore I protest against it. If you take away the stimulus of ambition and the wish to excel in any pursuit or work, so much more does the work become flat and stale, if not unprofitable; and if a man knows that by showing a superior capacity and superior zeal and energy, he cannot get ahead of the dull drone who works by his side, then he becomes a mere

machine; his faculties grow stunted and sluggish, and his physical perfection must also of necessity deteriorate.

The Progress of Hygiene.

Some cautious people are beginning to fear lest we may be going ahead too fast, and that some day when we find ourselves in advance of public opinion it may be necessary to call a halt. But take it all over, our modern developments of sanitary organisation have worked well and have given general satisfaction. But some will probably ask, "It is all very fine talking about fashion and popularity and progress, can you show any tangible results? Is the human race any longer lived, or better, or happier than in the good old days of pre-hygiene?" If you have any leaning towards the life conditions of Mediæval or past-Mediæval England, read Simon's "English Sanitary Institutions" and the "Health of Nations," and I guarantee that you will thank your stars that your lines have been cast in the cleaner and pleasanter places of the Victorian era. There is no doubt that the average sum of life has been sensibly prolonged. During the last quarter of a century the death-rate has been reduced from about 22 to 18 per annum, and whilst I give you sanitarians your full meed of praise for having abolished some diseases and lessened the incidence of others, we doctors intend to claim some credit too. We diagnose disease earlier and treat it far better, making much less demand on the constitutional vigour of our patients, and keeping in mind the good old principle that prevention is better than cure. As to the future, let Professor Matthew Hay, of Aberdeen, speak. He writes to me:—"Progress of the death-rate downwards must in the future be less than in the past. A death-rate of 10 per 1,000 would mean that everybody born lived to 100 years, or an average of that. Probably it will be found that the mutual elements of decay in men, as in all living things, which make eventually for death, independently of environment, will not permit of a lower general death-rate than about 14 to 15, even under the most favourable hygienic conditions reasonably attainable. So that by the time we have gone as far in reducing the death-rate as we have in the past quarter of a century, we shall have reached the ultimate minimum, but it will certainly not be in another quarter of a century." We can thus see a considerable material gain, but I claim for hygiene more than the mere prolongation of life—the betterment of it, the heightening of the mere joy of living, the clear and bright outlook over the horizon which results from good health. I am a great believer in the influence of physical causes over human affairs, and I commend to some of your ingenious and industrious minds the study of how far, at the supreme crisis of life, some preventable derangement has marred some great career. Temper and passions are often the result of temporary and probably preventable physical causes. Under the skilful guidance of Sir John Simon, and Sir George Buchanan and Sir Richard Thorne-Thorne, some of the most acute minds in England have been unravelling abstruse sanitary problems, and tracking out from clues invisible to the ordinary eye sanitary defects which were poisoning districts and embittering and destroying human life. But these are scattered and not always accessible, and I strongly commend to your attention two capital little books, which strike the nail very directly on the head. The first of these is by your respected townsman Mr. Pridgin Teale, who in the intervals of a brilliant and successful surgical career has found time to preach the doctrine that a nation's health is a nation's wealth, and to furnish a series of object-lessons of the most clear and practical, if alarming kind. The second is by our esteemed friend and associate, Professor Corfield, one of the pioneers of sanitary progress, and it is called "Disease and Defective House Sanitation." It consists of two short lectures, but it is crammed with suggestive matter, and he enumerates the following diseases as directly caused by the defects included in his title—sore throats, diphtheria, scarlet fever, blood poisoning, puerperal fever, pneumonia, diarrhoea, enteric fever and general malaise have all resulted from badly-connected ventilating pipes, badly-trapped waste pipes, defective drains, split soil pipes, foul pan water-closets, and very frequently from escapes of gas, a cause more especially of sore throats, new to me, I must confess. But short of the more formidable diseases included in the list, and which can be readily diagnosed and treated, there is no doubt that ill-defined symptoms of malaise and depression are often caused by sewer-gas.

The Defects of Civilisation.

What are the defects of modern civilisation? I have told you many of the benefits. In the seventeenth century the death-rate was said to be 7 per cent.; it is now about 18 per 1,000, but unfortunately for many of us, the advantage is mainly between the ages of five and thirty-five, and our chances of reaching this maximum period of longevity are distinctly increased. The majority of us are older than that, and we want to know what is to become of us, and vital statistics do not give us much comfort, for after middle life, when we stand on the tableland and look over the edge before stepping downhill, we

do not live longer and we break down sooner. Why is this? One evil of civilisation is the tendency to crowd into big towns, and Dr. Fan long ago showed that the rate of mortality increases as the density of population increases. Dr. Beddal says:—"Men seem in this climate and country to be most healthy where they see least of each other, where they produce and convey the least infection; in fact, where the proportion borne by man to nature is the most insignificant." No doubt a country life is often dull and monotonous, and the charms of town are numerous and varied, but I have a shrewd suspicion that many an emigrant from one to the other will end by agreeing with Professor Poore, that "as things go at present there is very little doubt that the agricultural labourer with his cottage and garden and 12s. a week (I may say in Scotland 15s. to 20s.), is infinitely better off than the town artisan on 25s., who pays dearly for pigging it in overcrowded rooms in which a cleanly and decent existence is impossible." We all know the drawbacks of big towns. Houses are dear and often bad, the air is usually poisoned with smoke, a nuisance on which Ernest Hart and others have expended much patience and labour, but which seems as far from being abated as it was twenty years ago, when we had congresses and exhibitions, and apparently a fair chance of getting something done. Then there is the difficulty of sewage disposal and the pollution of rivers, and the multiplicity of local and public Acts, some oppressive, some repressive and some progressive, which Parliament and other bodies inflict on us year after year. No doubt it is dangerous to be placed within easy reach of receptacles of foul air and sewer gas, as we all are, and necessarily must be, under the system of water-borne sewage, common to our great towns; but the greater the risk the greater should be the care exerted to keep it off. It would be a good thing if workmen, and more especially those who manufacture the complicated networks of machinery which modern hygiene requires, should not only feel but carry into practice the full sense of responsibility resting on them in connection with their trade. They should be taught how a bit of scamped work—a leaking cesspool or a badly placed or constructed drain, or a badly socketed soil-pipe, or any derangement in the mechanical contrivances designed to keep out the sewer gas which is always trying to force its way in, may destroy human life just as effectually as poison or the knife—and this is why I have persistently supported the plumbers' registration in and out of Parliament, being convinced as I am that without establishing a monopoly, or doing any real harm to any vested interest, the establishment of a defined curriculum, followed by registration and examination, will raise the status and character of the workman, and by increasing his sense of responsibility and his interest in his work, will not only confer benefits on him, but also on those by whom he is employed.

The Increase of New Diseases.

The next point I wish to refer to is one of considerable interest. It is the curious way in which, when we have abolished one set of diseases, another band of successors sometimes springs up to plague humanity. We have stamped out typhus under its various names of gaol fever, or black death, or plague, although I am not sure whether the recent epidemic at Ballymullet, in Ireland, is the old-fashioned spotted pestilence about which Stokes and Granes used to write, or whether it is relapsing fever, that gaunt spectre which followed in the wake of misery and famine. Enteric fever remains pretty stationary in the last ten years, but a drop of from 309 in 1876 to 175 in 1895 does credit to our sanitary administration, and phthisis has gone down from 26,443 in 1876 to 22,775 in 1894. Smallpox has taken a satisfactory dip downward from 2,405 in 1876 to 33 in 1895. Measles, scarlet fever and whooping cough have killed fewer than formerly, but per contra diphtheria has largely increased, and the reason of that no doubt is, as Sir R. Thorne-Thorne says in a most interesting private communication I have received from him, "the ever-growing facilities for personal infection, and other similar points, have followed on the success in herding our child population into elementary schools at the very age at which they are most susceptible to this disease." Other diseases have also increased, and the point I wish to make is this—that they are mostly diseases connected with the nervous system, and that Crichton Browne is probably right in his opinion that not merely the nervous temperament but the neurotic diathesis is on the increase among us. To begin with, it is a mournful but, I fear, an undoubted fact that more people go mad than formerly. I have not by me any statistics to prove this beyond the report of the Registrar-General for 1895, but there I find under the heading of insanity and general paralysis, a disease which was seldom or ever heard of in former years, 3,620 deaths in 1895 against 933 in 1876. Angina pectoris, a typically neurotic disorder, has increased within the same period from 397 to 696; tubular disease of the heart, which has some practical sympathy with the neurotic diathesis, has gone up from 274 to 10,072; whilst Bright's disease, the frequent causation of which by sudden mental shock has been demonstrated by

Clifford Albutt, shows an alarming rate of increase from 4,100 to 8,351. Cancer, to which, in absence of any better explanation, I must ascribe a venous origin, has nearly doubled since 1876, whilst diabetes reached its highest point in 1895, accounting for 2,265 deaths over 910 in 1876, and most of us know only too well the firm grip taken by influenza on the British constitution, and the way in which in more recent years it has attacked the nervous system and damaged both weak and strong points with a zeal and discrimination too often permanent in its effects.

A Neurotic and Anæmic Age.

There seems no doubt, therefore, about the fact that we are now in the midst of a neurotic age; and the next note of interrogation is, Why? The answer to this, if there be one, would require a course of lectures rather than one address, and all I can do is to indicate one or two suggestive considerations which perhaps some of my successors, or some of you sitting before me, may work up. About the time I began my medical studies a furious controversy raged in Edinburgh concerning the treatment of acute inflammation, one side affirming that there had been a change in the type of disease, whilst the other affirmed, and to my mind more successfully, that the change had rather taken place in the constitution of the patient. At all events, the bleedings and blisterings and purgings, amid a succession of which the sufferers of former days passed peacefully out of existence, have given place to careful nursing and feeding and moderate stimulation, and results which enable the medical man to rank along with the sanitarian as the prolonger of human life. But why this change of constitution? Some ascribe it to the stress and push of this competing age, when berths are few and men are many, and when the margin of subsistence trenches too closely on the means of support. This sort of reason has always seemed to me both feeble and unsatisfactory as well as non-convincing, for is it not those who are removed by fortune from the whirling maelstrom of life into quiet backwaters who suffer most from nervous affections? Who is it who have the neuralgias and the hysterias and the heart failures which send them to Schatt and Neuheim, and the nervous prostrations which attack both sexes alike, and which sometimes seem to me to come from blue rather than red blood? Not the strenuous workers in the hive, but the drones, who, more by chance than design, and from lack of opportunity rather than deliberate idleness, lose the healthy stimulus of occupation and spend their time in that most wearisome of human occupations—trying to kill it. And now I think I have a clue. This is also essentially an anæmic age. How many young girls in any rank of life escape passing through a bloodless stage, which suggests a strike or lock-out among their red corpuscles and a consequent stagnation of those vital processes which depend on their active functioning? Some one has described neuralgia as the cry of starved nerve roots for a healthy blood, and may not modern nerve derangement be due to this deficiency of the most vital element of our vital stream? Let us take another glance at the Registrar-General's report, and we shall see that deaths from anæmia, chlorosis and leucocythæmia have advanced from 576 in 1876 to 1,883 in 1895. A glance at the cheeks of the rising generation must convince you that this increase of pallor is only too real. Then why is it? Ask your medical friends (for on this occasion I am only a sanitarian), and put before them these special points. Has anæmia anything to do with too much meat-eating and too little milk and oatmeal and fruit and vegetables? Is it connected in any way with our pressure at schools, or has our old friend tight-lacing anything to do with it, in other words, what is the explanation of the undoubted fact? And when you have received the information from your medical adviser I hope you will come and tell me all about it. So much, then, for civilisation and its defects. Have I anything to suggest for the improvement of the human race? Evolution is still going on, and I have some suggestions to make towards the formation of a Sanitary Utopia, the capital of which shall be our lamented friend Sir B. Richardson's City of Hygeia, where we should all like to live and move and have our being, if we could get the chance.

The Value of Light.

We should be exacting in the matter of light, and light should even face the fading of a drawing-room carpet rather than have blinds drawn down and windows closed until what we Scotch folk call "the room" is about as close and musty as a ship's cabin in mid-ocean. Remember that the sun's rays kill bacilli and encourage the processes of life, cheering the sound and aiding the recovery of the sick, and even its imitations are useful, for Sir W. Preece found at the General Post Office Savings Bank Department that electric light diminished the sick absence by two days per head per annum. The difficulties of water-borne sewage will have to be vigorously faced some day, and I agree with Dr. Poore in hoping that the manurial wealth annually squandered and rendered useless by dilution and antiseptic admixture may some day be utilised for the good of the earth as effectually on a large scale as he has shown it can be on a small scale.

The Secret of Long Life—The late Sir I. Holden.

If time had permitted I should like to have traced the budding citizen from the period of adolescence at twenty-three years of age to maturity, when the leaf is fully developed at forty-five, until decline sets in at sixty-seven, and the green turns to russet, and finally bidding him farewell, when the branches begin to grow bare "and autumn's falling leaf told to the old man he must die." Let me give him a word or two of advice before we part. If he wishes to live long he will have the best chance in Norway and the worst in Ireland, and it is well to be a Jew, because the strongly vitalised and aptly christened "Ancient People" pass four score and five years of life in the proportion of three to one of those among whom they are cast to live as fellow citizens. Long life as well as the full enjoyment of it while it lasts depend on three conditions. First, a good digestion. You must put yourself under medical guidance for this, and your doctor's attention should be largely directed to keeping you clear of uric acid, that pest of advancing years, which teases us with gout, and the origin of which seems to depend a good deal on intemperance in the use of red meat, and perhaps of tea, coffee and cocoa, which contain, according to Dr. Haigh-Zanthin, a chemical substance which is speedily changed into a tormentor. Second, on the integrity of the heart and great vessels, and if we have been strictly moderate in the use of alcoholic drinks, and not put ourselves in the way of catching those euthetic diseases which have so much to do with atheroma, we may hope to keep our muscular system in a state of integrity until tolerably advanced years, barring accidents, of course. In the late forties the degenerative changes are apt to set in, and rigid arteries suggest that we should moderate our pace and walk rather than run. My old friend, Sir Isaac Holden, who lately ended his most honoured and useful life at the age of ninety, was very fond of expounding his dietetic scheme, which largely depended on the avoidance of salts of lime, as contained in bread and water, and which, according to him, became deposited on the coats of the arteries, and led to brittleness and cracks and apopleptic seizures. He ate a great deal of fruit and vegetable, and very little meat, and partook most sparingly of alcohol, and a month or two before his death, when I met him in London, he looked in most perfect bodily vigour, and had all the appearance of a man of seventy or seventy-five. His death might really be called premature, and illustrates the well-known fact that the old get along all right as long as the road is smooth and flat, but they do not triumph over obstructions which would hardly affect a younger man. For I believe it was from the effects of influenza that this remarkable man was removed from among us. Third and last. Sustain the nervous system in good repair, and this simply means—general bodily vigour. Good regular work is essential to keep people's minds from pressing too much on their bodies, and it is interesting to note with Dr. Beard, quoted by Richardson, that the average age of 500 of the greatest men in history was sixty-four, and Madden gives a list of 220 illustrious hard mental workers who attained to an average of sixty-six years. Then how long should we live? Professor Owen used to say as long as our teeth, but dentists have altered all that. Richardson says ninety years. Dr. Farr extends the space to 100, and Lady Glenesk in her recent article in the *Nineteenth Century*, makes our claim on longevity run as far as 120 years. And the moral of it all is—that we should try to live as long and as well as we can, and teach our children to do the same, saying with old Adam:—

Though I look old, yet am I strong and lusty,
For in my youth I never did apply
Hot and rebellious liquors to my blood.

The Housing Question.

Finally, a word on the housing question. What is urgently needed is, firstly, drastic radical legislation, by which local bodies may be able to acquire land compulsorily, on paying full compensation, for building workmen's houses, and then quick and cheap railway travelling, rendering it possible for city workmen to live in the surrounding country. As Dr. McVail puts it in a letter to me:—"This is a sanitary measure which may have a great future before it. Houses built in the country for such a purpose would not have the defects of damp and disrepair which belong to the dwellings in a decaying agricultural village. Such dwellings would have the advantages both of town and country, and natural advantages of fresh air and rural surroundings and the artificial advantages of houses built according to city requirements; and with shorter hours of labour the artisan will have plenty of time to travel backwards. Light railways will do much to help in this direction, and it does not require me to sing the praises of well nigh universal weal."

Parliament and Health Questions.

But we must now leave Utopia and come back to this work-a-day world, which, after all, is not such a bad place to live in if we treat it properly. As I have already shown, each of us is individually responsible to ourselves and to others for

our scheme of sanitation, and then we pass into the hands of local authorities, who are doing good work, who generally give you value for your money, and whose beneficial operations I hope you duly appreciate. But over them stands the House of Commons, and I am glad of this opportunity of saying that I have a very poor opinion of that legislative assembly in its dealings with public health. Both sides are bad, but that to which I belong, I think, the worst, for a suspicion of scientific methods and of progressive sanitation is deep-rooted in certain Radical quarters, and abstract views of personal liberty and distrust of the so-called tyranny of doctors sway a kind of plausible sentiment which is usually irresistible in its paralysing effects of hygienic legislation. As a member lately remarked with refreshing frankness when we were considering the Public Health (Scotland) Bill, "When I see the doctors on both sides of the House agreeing, my instinct tells me that something is wrong, and I will vote against the amendment." Under such conditions the private member can hope to do nothing, but he may be still usefully employed in stimulating public opinion in and outside the House, until particular problems reach the acute stage and are taken under Government protection; and, as one last word, let me reiterate the strong wish I have already publicly expressed in favour of a Ministry of Health, a department of the State which will collect and co-ordinate into one harmonious whole the scattered threads of sanitary legislation which entangle and frequently perplex every one of our great Parliamentary officers, which would focus all health questions and furnish a bureau of information which would enable us to see at a glance what is going on elsewhere, an admission to which would be an object of honourable ambition to the best scientific talent of the day.

BEDFORD CASTLE.*

FOR the matter of the notes which I have to offer on this historic site, I beg to say that I am almost exclusively indebted to the writings of some able Bedfordshire archaeologists. I propose to preface my remarks on the castle with some allusions to the early associations of the locality.

It appears that Bedford was not a military station of the Romans, and no Roman name has been found for it. Camden says it cannot be identified with the Lactodorum of the Itinercaries, for it is not on a military road. It is situated, however, on a vicinal or bye-road—that which branched off from Sandy (Salinæ), and after passing through Elstow and over the ford here, went northwards to join some of the Roman stations on the river Nenn. A portion of this road, on the south side of the river, is identified with Potter Street, and (as we have heard from Mr. G. Hurst this morning) skirts the south side of St. Mary's churchyard, forming the boundary between the parishes of St. Mary and St. John, and then turns towards the river at the place of the ancient ford, which is supposed to have been nearly opposite to the Castle Mount. Roman pottery has been found in Potter Street, also in the Market Place. It is probable that British earthworks for the protection of the ford stood on this spot. There was a defensible stronghold here at the time of the Saxon invasions, for we read in the Saxon (or Old English) chronicle that in the year 571 Cutha or Cuthwulf, brother of Ceaulin, king of the West Saxons, overthrew the Brito-Welsh in a great battle at Bedicanford, and took four towns; and nine years later, A.D. 580, Ceaulin himself took the fortress of Bedicanford and seven other towns. The Romano-Britons appear to have made a desperate resistance here. This earliest form of the name, "Bedicanford," may be explained to mean "the ford protected by an earthwork," from the Saxon "Bedician," to bedike, *i.e.* to fortify with a dyke (a rampart and ditch). Several other etymologies, however, have been proposed by antiquaries.

In Mercian times Bedford seems to have been a place of some importance, and a favourite resort of King Offa II., who, we know, was buried with royal pomp in his chapel here in 796. Matthew Paris says this chapel was outside the town, on the banks of the river Usca (*i.e.* the Ouse), and some ages after the chapel and tomb had been swept into the river by floods they were still visible to bathers during the summer droughts. It is possible the chapel was built on an island; the traditional site, however, is near the wharf called Batt's Ford, on the north side of the river; it is nearly opposite the site of Caldwell Priory. According to King Alfred's compact with Guthrun, Bedford, being north of the Watling Street, fell within the district afterwards called the "Danelough." It has been remarked by Mr. Douglas Elwes, that in Bedfordshire there are no local names terminating in Thorpe or By (Danish words for village and dwelling), whence he infers that this county was never permanently settled by the Danes. In 919 (according to the Saxon Chronicle), King Edward the Elder marched to Bedford, and having gained

* A paper read by the Rev. Henry Fowler at the visit of the St. Albans Archaeological and Architectural Society, and published in the *Herts Advertiser*.

the town, remained thirty days and ordered a burgh to be built on the south side of the river. Hoveden says that this was called Mikesgate. This section of the town has been called from time immemorial Potter Street ward (which, as we have heard, Mr. Hurst derives from the Latin "Porta"); he has also suggested that the pre-Norman work in the tower of St. Mary's Church belonged to a watch-tower of Mikesgate, and that the church was built on to the tower. In 921 a Danish host marched from Tempsford (Tamis Ford), about 6 miles down the river, and made a desperate attempt upon Bedford; they were repulsed by the brave burgesses with great slaughter. It is inferred that the ancestors of the people of Bedford were Saxon or East Anglian rather than Danish. There were Danes, however, even among the abbots of the primitive monastery after it had been reinstated. In the year 1010 the town was taken and burnt by the Danes (Saxon Chronicle). The churches, we presume, must have been in great measure destroyed and rebuilt soon after this date. I must pass on to the Norman period and the story of the castle.

After the Conquest the barony of Bedford was conferred on Hugh de Beauchamp, a great lord who came over with Duke William, and was rewarded for his services with forty manors in this county. In the Domesday Survey Bedford is rated at half a hundred. The Hundred Norman Castle was built by Hugh's second son, Paganus (or Payne) de Beauchamp, in the reign of William Rufus, and so before 1101. It was clearly a place of great strength, for it was an object of contention during all the civil commotions till its destruction. The castle was erected on this site, I mean the mound on which we stand, and what is now the beautiful garden of Mr. L. C. Higgins; this is probably identical (as I have already mentioned) with the site of the Saxon fortress. The mound is large enough to have been the site of the keep or dungeon, for its summit is 150 feet in diameter (I am quoting from the account of Mr. G. T. Clark, the great authority on castles); he says it is only 15 feet high, but from the bottom of the fern-covered ditch it looks like 25 feet. It has been levelled down and may have been twice as high originally, in which case, of course, the summit would have been much smaller. The situation of the Norman keep, however, is debated by antiquaries. Mr. Higgins informs us the strong tower was probably in about the position of his present house. I will return to this matter by-and-by. The burgesses of Bedford, sturdy men as they were, had, of course, to bow to the great lord who was their patron, although they had their immunities by prescription, and probably were assisted in maintaining them by the canons of the collegiate church of St. Paul, who appear to have been lords of the borough manor. The borough obtained its first charter in Henry II.'s reign. There is some discrepancy in the authorities in regard to the earlier sieges of the castle, and no little confusion about the relationships of the Beauchamps, its owners. I will follow the account given by Mr. Dudley Elves in a paper written in 1874.

Milo de Beauchamp, the son of Payne, was attacked here by Henry I., and driven from his castle. Nothing more is known of this, but he seems to have recovered favour and to have been reinstated, for we find him and his brothers holding the fortress in defiance of King Stephen in 1136, when the king was bent upon depriving him and bestowing the barony on Hugh de Bellemont, brother of Robert, Earl of Leicester, to whom he had given in marriage Milo's sister, Maude de Beauchamp. Dugdale states that the castle was then "a place of great strength, with a mighty rampart of earth and a wall enclosing an impregnable tower." The king failed in his assaults, but after a long siege the garrison was starved into surrender. Milo and his companions-in-arms, who had friends at court, were allowed to march out with honours. It is very doubtful whether Hugh de Bellemont was ever put into possession, for the Barony of Bedford was annexed at this time to the Earldom of Huntingdon, which had been granted to David, King of Scotland, and (according to Holinshed) his son Henry was enfeoffed. In 1138, when David had espoused the cause of his niece, the Empress Maud, Stephen marched against him, and on his way sat down before Bedford Castle, which is said to have been garrisoned by the Scots. Meanwhile David burst into Northumbria, and (says Matthew Paris) committed the most horrible slaughters and devastations. The castle was taken in thirty days by a succession of fierce assaults, the first being delivered on Christmas Eve, and the fighting carried on through the festival of "Peace and goodwill." After the capture the Beauchamps seem to have recovered the barony by Stephen's favour. Simon de Beauchamp, the king's steward, was probably the son of Milo, although the chroniclers call him the son of Payne (the dates requiring this correction). In 1155 he was at strife with King Henry II., and held the castle against him. On its surrender the burgesses who were found in the fortress with him were mulcted in a fine of 20*l*. Simon's lands were then taken into the king's hands. He was a great benefactor to the Augustinian canons of St. Paul, established here by his grandmother, Rohesia, or Roysse, de Beauchamp, widow of Payne, the founde

of the castle. He removed the community to a new habitation which he provided for them at Newenham, about a mile down the river, and was honoured as their founder. He was the holder of forty-four knights' fees in the honour of Bedford, which he does not appear to have forfeited. Under Richard I. he recovered the governorship of the castle by paying a fine of 100 marks. Richard I. confirmed the charter of liberties to the burgesses. Simon died in 1207-8, and was buried (says Leland) before the high altar in the church of St. Paul, Bedford; the patronage of this, doubtless, remained in the hands of the canons. The priory church of Newenham was also dedicated to St. Paul, as the seal of the convent shows.

In the turbulent reign of John, the Beauchamps upheld the patriotic combination of the barons. William de Beauchamp, the son of Simon (who paid 500 marks and six palfreys for livery of the lordship on the death of his father), had served under the king in several military campaigns. When the rupture occurred he sided with his peers, and in the spring of 1215 opened his castle to the baronial forces, who had failed in their attack on Northampton. Shortly after this the angry king sent his favourite, Faulkes de Breauté, with an army to demand the surrender of the castle. It was given up in a few days without fighting. The cause of this is left in obscurity. Probably the place was not provisioned for a siege, for there was no lack of bravery in William de Beauchamp, who was among the staunch men who enforced the signing of the Great Charter at Runnymede. The castle and barony of Bedford were conferred upon Faulkes as a reward for his services. He was a man after John's own mind. He had been brought over from France by him in a mean capacity, and had been advanced on account of his military abilities to considerable honours and emoluments, and had been married to a rich heiress, Margaret de Redvers. We heard of him when we were at Luton, about seven years ago. He built a castle at Luton in 1221. The "Monastic Chronicles" are full of his deeds of violence, spoliation and sacrilege. It appears that as soon as he was put in possession he set about fortifying the castle on a grand scale, thinking to render it impregnable and to secure himself against all interference in his lawless practices. To provide himself with materials he pulled down St. Paul's Church without remorse and partly demolished the buildings of Newenham Priory and of some other religious houses. John cared for none of these things, or rather, according to documentary evidence, he sanctioned them; but the loyal supporters of his youthful successor, Henry III., were of a different mind, and in due time retribution came. Matters were brought to a head in 1224, when judgment was given against Faulkes on thirty indictments of wrong by the king's justiciary, Henry de Braybrock. He refused to appear and was thereupon fined 3,000 marks. Faulkes in his rage sent an armed band to Northampton, seized the judge and shut him up in Bedford Castle, where he was treated with great harshness. To avenge these wrongs and outrages the forces of the kingdom were set in motion. And we are now brought to the closing scene of our story. Preparations for the siege were made on the largest scale, for it was a most formidable undertaking.

The late distinguished antiquary, Mr. Hartshorne, has given the fullest account of it, but I have not had the advantage of seeing his paper. The king held his court at Dunstable, and presided over the preparations in person. The leading peers and ecclesiastics of the realm brought to him their contingents and subsidies. Archbishop Stephen Langton, the Primate; Eustace, Bishop of London, and other prelates and abbots who were of the number, pronounced a solemn excommunication against Faulkes and his associates. Each of the prelates furnished two labourers from every hide of land which they possessed. The Sheriff of Bedfordshire looked to the provisioning of this great host, which included quite an army of miners and sappers, carpenters and labourers, for working the engines of war, and the operations were pushed forward with vigour. Faulkes, who seems to have considered his defences perfectly secure, after victualling the castle for twelve months, had withdrawn to Chester to foment disturbances in Wales, leaving his brother William in command. The siege commenced on June 20, 1224, and lasted two months. Matthew Paris informs us that the besiegers erected a lofty wooden tower, which enabled them to observe the movements of the enemy, and discharge their artillery upon them with great effect.

The account given by the Dunstable chronicler, who was a contemporary, is this:—"The castle was captured by four assaults. In the first the barbican was taken; in the second the outer bailey, in which they took possession of a great number of horses, munitions of war, live pigs and stocks of provisions—the barns stored with grain and hay were set on fire. A considerable share of this booty was bestowed on the brave men of Dunstable, who led the attack. In the third assault the walls next to the Old Tower (we may suppose 'the Norman keep') were overthrown by mining, and the inner bailey was occupied. The miners were protected by a machine called 'the Cattus.' Here ten of the king's men were caught by surprise and shu

up in the tower. Others were killed by the falling of walls. In the fourth assault the tower itself, having been mined, was split asunder by the combustibles which were applied beneath it, and the defenders were smoked out of their habitations. Thereupon they sent out Faulkes's consort, the judge, Henry de Braybrock and other prisoners; the next day they gave themselves up. On the morrow (which was August 24) William de Breaute and eighty of the garrison were summarily condemned to be hanged for their treason, and after having been absolved from their excommunication they were hanged on gibbets at the foot of the mount." Matthew Paris has drawn on his MS. a picture of the scene, with the king's standard flying from the summit of the keep. In the castle was taken an immense amount of treasure and booty of all kinds. Three Knights Templars from Caldwell Priory, who were among the defenders, received a pardon on condition that they went to the Holy Land. Strange to say, the traitor Faulkes escaped capital punishment. He soon came to throw himself on the king's mercy, pleading some former services, and that he was pledged to go on a crusade. His sentence at length was commuted for perpetual banishment, with the confiscation of all his castles, lands, treasure and plunder. His wife received protection. He went to Rome, and is said to have died in abject poverty at St. Ciriac in 1226. The king gave orders to the sheriff of Beds for the destruction of the castle. The great tower and the works of the outer bailey were to be demolished and the moats filled up. The inner bailey was to be partially preserved. The directions about the disposal of the building materials are of some interest. The mandate runs:—"Let one portion of the tower and walls of the ramparts be assigned to the prior and canons of Newenham; another to the prior of Caldwell (of course, in compensation for the injuries they had sustained); a third portion for the work of rebuilding the church of St. Paul in Bedford; and a fourth portion to William de Beauchamp, for the construction of his habitation." William de Beauchamp also obtained the castle site and the Barony of Bedford. He had made his peace with the king in 1217, and had restitution of his estates. He was a man of high character, and was subsequently sheriff of Beds and Bucks. He is supposed to have built his house in the inner bailey, the walls of which were left standing to half their height for his accommodation. The Beauchamp name here died with him. The site of the ruinous castle came to the Mowbray family by marriage with one of his daughters. I may just notice that the property, after passing through various hands, was purchased from the Gostwicks (in about 1730) by Sarah, Duchess of Marlborough, and then passed to the Dukes of Bedford.

FLODDEN AND FORD.

A CORRESPONDENT of the *Scotsman* writes:—"The Flodden of to-day lies in a richly prosperous piece of country. The "airy brow" of hill from which King James descended to meet his enemies is now fringed by well-grown woods. The plain which lay between him and his land is fat with crops. The Till winds its sinuous way by meadows, where the cattle stand knee-deep in succulent pasturage. It is a treacherously smooth river, still fulfilling its boast that for all its slow going it drowns twice as many men as the turbulent but honest Tweed. Red with the best blood of our country this murderous Till ran on that Black Friday on which Flodden was fought. Its gory flood carried to the Tweed the news of dire slaughter. It is difficult by reason of the peace and plenty which now reign on that once debateable land to follow in the prints of the olden wars. Great castles, such as Norham and Twisel, still magnificent in their decrepitude, show how strongly guarded once upon a time was this border. Peel towers on the north side, from whence the stirring Scots raided forth, stare over at their English rivals. These peels to-day are now mostly found cased round by farm buildings, which shelter only honestly bought beasts. In an old peel not far from Berwick, still used as a dwelling-house, the flooring on the lower flat being lately renewed, there clung to the soil the red hair of cattle lang syne driven hastily in to the tower to keep them from some acquisitive moss-trooper. But the whole of the broad border is now so thoroughly under the dominion of the plough that the era of the sword seems almost mythically far past. Tall is the wheat and full eared in the field where a pillar marks the spot where King James fell surrounded by that valiant rampart.

Every stone a Scottish body,
Every step a corpse in mail.

He could with but a handful of the stubborn spearmen who there formed that "dark, impenetrable wood" around him have checked the English at Twisel Bridge, but Pitscottie tells us with a fatal love for a fair fight James refused to take advantage of the English in the narrow defile, declaring "that he was determined to have his enemies before him in a plain field."

There was a quixotic dash and chivalry in James which made a hero of him. Erring though the hapless Stuarts in succeeding generations were, they too attracted their followers, they brightened the pages of history with a romantic glamour, which even now blinds one to their faults and stirs our sluggish "fin de siècle" blood into enthusiasm. By Sybil's Well the thirsty pilgrim of to-day can rest and drink. The little fountain cell has engraven on it the words of the wizard who immortalised it. It was from this spring likely our troops drew water as they lay idly waiting while Surrey crossed the Till and cut them off from Scotland, so that when the armies met they each faced the land they loved the best. The English looked to the south and beyond the green swelling outline of the Cheviots saw their homes. The invading Scots fought with their faces to the country beyond the rippling Tweed. Evidences still tell of the rich harvest that the Great Reaper garnered on September 9, 1513, on that border field. Swords long hid have again in this century seen the sun, and sometimes the ploughman's course is impeded by a stone cannon ball. Shortly before Waterloo was fought some ground on Flodden was drained, and there came to light a long trench of bones—the sepulchre of the forbears of many of us, for but few Scots live who did not lose an ancestor on that field. Two ladies told a neighbouring rector in the early years of 1800 as children they used to gallop their ponies over a still uncultured Flodden. Nothing in the shape of gates or crops stopped them from careering over the country till they reached the bracken-covered slopes of the Cheviots, topped by storm-stricken thorns. That "plain field" whereon James elected to meet his foes till comparatively recently was guiltless of cultivation. Till this century it was as untutored as when our kingly squire of dames took his three steps into English ground to please the Queen of France. She sent him a turquoise ring, and charged him if he were a worthy knight to break a lance for her sake and harass their mutual enemies, the English, on the northern border while France kept her alert with warlike preparations in the south. King James had been married full thirteen years then to Margaret Tudor. Some jewels he thought her due had been withheld from her dower, and this made him all the readier to take up the Queen of France's challenge. His appetite for battle whetted by her turquoise ring, he eagerly set forth to war on England and take from it in land the value of Margaret's jewels. To prove his prowess he captured Twisel, Etal and Ford castles, and there paused. Sir William Heron, the owner of the latter, was a prisoner in that secluded hold, Fast Castle (better known to us as Wolf's Crag), but his wife unfortunately remained in Ford and wiled the too susceptible and gallant king to dally there. The room he slept in before the battle is still shown. From its windows we look on the gardened Flodden of to-day, where the prime of our land fought so well and bordered the pages of our history with mourning. That saddest story of dule and woe bore in time the fruit of sweetest song. England lost her thousands, too, but they were only her pawns in the chess-board of war. In these past days it was the loss of those of high estate which made a battle memorable, nay, even a paying concern to the victor if he captured nobles and knights of renown. It was the levelling radicalism of shot and shell, *versus* the more select bow and spear, which took away the revenue of these fighting nobles of old, by bullets finding a fatal billet in a knight as readily as in a man-at-arms, and leaving to the victor no wounded, sought-after grandee to hold as hostage for a ransom. At Flodden, king, bishop and knight fell before the English archers. Not only in the green loanings which traverse the Border was there sighing and moaning for these bonny men, the Flowers of the Forest, but Westland lairds and ladies under the dule trees by their castle doors wept for sons and husbands who had gone forth with their followers to Flodden, never to return. There, where to-day the corn yields a full harvest, the carnage raged, till the pall of night hid the enemies from one another. Then jaded, beaten men escaped in the darkness to spread the news of that fatal field where our royal standard received its most costly dye—the life-blood of its king.

Ford, like many Border strongholds, was famed in these olden times for its warlike spirit. Its smiths hammered stout armour and forged deadly blades for the castle's guardians, but now, when all need of constant skirmishing is gone, it is famous in these piping times of peace for the brush. Art has eclipsed war, and many journey to the thatched beflowered village which lies under shelter of the strong castle of Ford to see in its school the walls lined with wonderful frescoes. Lady Waterford, one of the "Two Noble Lives" Hare has written, wrought marvellously well on these school walls: The Ford children whose ancestors had been the wielders of the sword do their daily tasks in a gallery created by the brush of a genius. Their idea of the childish Bible characters will be clearer than most. Cain and Abel, David the shepherd boy, Esau and Jacob, Moses and Samuel, &c., are all there before them graphic and life-like. Our first thought is that so much beauty of design is wasted on these careless scholars; but who knows what fru

the learning of lessons within such lordly walls may not bear? It is an education in itself; they must carry out with them into the battle of life many recollections woven into their hearts by that well-endowed schoolroom. Some puzzle in the multiplication table they could not answer will be fixed in their minds by the recollection as they stood up facing the master of how their thoughts travelled from seven times seven to the portraits of the Johns, Evangelist and Baptist, which flank the teacher's desk. Copy-book maxims they slowly indited will be associated with the pictures on the walls their inattentive eyes fixed on—of Christ before the doctors, where the figures of each stand out at the end of the schoolroom so life-like as almost to seem to move. The picture of the little children He begged to come unto Him faces that of the Boy Christ in the Temple. The little ones anxious to gather round Him are the counterpart of the children who do their daily tasks below that fresco—rosy of cheek and hair bleached fair with the sunshine. It was their mothers and fathers who sat as models to Lady Waterford. Big men grimy with their toil on the neighbouring coalfield will point out to their sons lint-locked, smiling bairns in the frescoes which were exact portraits of them when they were in petticoats. The Bible stories and Bible people are brought very near to the inhabitants of Ford, for they are familiar with them from the time they learn their A B C, and it is small wonder if Ford folk should be better than their neighbours. The frescoes are turned round with flowers, and the pictures they frame are ever with them—evergreen in their memories. The village, which in olden times grew up round the castle to hold the Herons' vassals, is model and picturesque. The people look out on the stately column their Lady Waterford reared to her husband, who "had no son to keep his name in remembrance." He had read this verse from Samuel to her on the morning of his death, when he went out to the hunt, a man in the heyday of his strength. He was carried back to his home dead before eventide. To his widow he left the castle of Ford, which she restored and decorated. Little of the walls which beheld the fight had been left by former owners, but King James's tower remained intact. It overlooks the battlefield, and, like the rest of the dark stone pile, it stands, as it were, on a bed of roses, for terrace on terrace of these red flowers surround this dark Border castle. Across Ford's drawbridge the English herald, Rouge Croix, rode when James was making preparations to fight. He had refused to listen to the counsel of his barons to retrace his steps. It was at Ford that he bid Archibald Douglas, Earl of Angus, to "Get home if he were afraid." Choking with tears the aged Bell-the-Cat replied, "As long as my body was able to undergo hardships, I never spared it for the public good and to maintain the honour of my king; but since now I am useful only for advice, and the royal ears are shut against it, I will leave my two sons who, next to the nation, are most dear to me." He gathered his convoy and forthwith left. When a bearded man was forced to weep, and that man a Douglas, James was deaf indeed to advice. Through our country's history, foremost as doers of doughty deeds always came a Douglas, for

Never king did subject hold,
In speech more free, in war more bold,
More tender and more true.

It was not only the men who bore that name who were aye ready to face danger. Catherine Douglas's arm supplied in the staple the place of the missing bolt, which, till it snapped, barred the door against James I.'s assassins. Down where now the damask roses cluster rode the mortified and heart-broken old earl, who saw his king and his sons no more. Flodden killed him, for the heaviness of that blow weighed him down, and he died the ensuing year in the monastery where he had retired after that storm of sorrow had swept over Scotland. The going and coming of the heralds before James threw down the gauntlet of war must have been a lordly sight. Lady Waterford could conjure up these old-time diplomatic formalities, so full of scenic display, for she saw a this century tournament at Eglington and there first met Lord Waterford. In her room at Ford still hangs a portrait she painted of her own true knight.

It is difficult to leave Ford, so full and fascinating is it of a past of war and pageants, a present of flowers and art; but the sun is turning to the west and we are a far cry from home. We have to cycle to far beyond the Tweed, and turn our backs at Berwick on what Johnson epitomised as the finest view a Scotsman can behold, the road to England. So we are forced to leave Ford ensconced in its roses and green woods and Flodden arrayed in its fertile garment of corn, and we pass the false Till at Twisel Bridge and the noble Tweed at Norham. It was to Norham's castled steep a Marmion before Scott's came with his golden helmet and tasted of blows from mettlesome Scots, as his lady had commanded. We speeding north after having left Berwick a few miles behind us pass by Lammerton Farm, which stares out on the grim North Sea. There once stood a tower in which Margaret Tudor halted on

her bridal progress. It is well past "our good town of Berwick" and all its debateable land. Sure she was on undisputed Scottish soil, she was there married by proxy to James Stuart. The royal marriage seemed fraught with dissension. The jewels she did not bring with her were the ostensible reason of England's being invaded and Flodden fought. Margaret, if all tales be true, had but a sorry time of it as King James's wife. Her signature scratched in a good hand on the wall of Falkland Palace was recently there found, and is now sheltered under glass. When she first wrote "Margaret" in Scotland one wonders what she thought of the kingdom she had come to rule over, if she longed in the after years to return to her gentler south country. Her courtiers little dreamed, when she became wife of James IV. at Lammerton, that she dowered Scotland and her heirs with the succession to the crown of England. Flodden was the last great battle between her land and ours, for it was she who was the means of bringing about a lasting union between the sister kingdoms, and turned our bitter enemies, the English, into our peaceful fellow-subjects.

CHURCHES ON THE EAST COAST.

THE Ecclesiastical Commissioners, says the *Norwich Mercury*, it is reported, will decline to accept any site for a new church near the sea along the stretch of east coast from Yarmouth northwards. The matter has arisen at Mundesley, where the old dispute between the possible restoration and a new building is being fought out. The decision of the Commissioners is certainly a wise one. Visitors to this coast must have been struck by the old deserted churches that stand at the sea's edge at intervals, "solitary warders of the deep," waiting for the storm that will bring them down as the sea encroaches on the crumbling land. Cromer old church went under the waves long ago. The old tower at Eccles, of which Chaucer makes mention, went down in the great gale two years ago. The most notable of the remaining old sanctuaries is the Sidestrand tower, which stands amongst its graves right on the cliff's edge. A corner of the old churchyard has already gone down, and some morning the people of the district will undoubtedly look for the familiar old landmark and find it gone.

THE STABILITY OF MASONRY ARCHES.*

FROM the time of Newton the theory of the arch has been discussed by innumerable writers, among whom, as the most noted, may be included Gregory, de la Hire, Coulomb, Eytelwein, Navier, Lamé, Poncelet, Moseley and Rankine. All of these, with the exception of Navier and Lamé, seem to have accepted the so-called statical theory, stated in its clearest form by Coulomb in 1773, and treated with the greatest mathematical elegance by Moseley in England and Scheffler in Germany.

Since the introduction of railways, however, the importance of taking into proper consideration the heavier moving loads has caused the statical theory to be regarded as not altogether equal to the conditions, and the increasing knowledge of the properties of materials under stress, together with the widening appreciation of the importance of considering the question of elasticity, has led engineers to believe that the elastic theory should also be applied to the arch, whether built of masonry or of metal.

The elastic theory, as applied to arches, is due to the researches of Bauschinger, Köpcke and others, and appears to have been first clearly stated by Winkler in 1867, followed by Weyrauch in 1879, and Müller-Breslau in 1886, and has been most fully confirmed by the important experiments made by the Austrian Society of Architects and Engineers from 1891 to 1893, and published in 1895.

Under the old statical theory the stone was supposed to be rigid, and when the equilibrium line approached too near the outer limit, "rotation" was assumed to take place, the joints on the opposite side of the voussoir opening and the entire structure suffering distortion. The only resistance which the stone was supposed to offer was based on its ultimate crushing strength, and the question of its elasticity was not taken into account; indeed, its modulus of elasticity was rarely found.

It is evident, however, that if we consider the material as possessing elasticity, the yielding of the voussoirs at the points under greatest pressure might cause a tendency to rotation, and consequent opening of joints, long before the crushing strength was approached, and that, when the load which caused this action was removed or shifted, the parts might resume their normal positions and relations without having suffered any permanent deformation, while, if the yielding to unequal pressure was sufficiently great, the portions under tension

* From a paper by Mr. H. H. Supplee in the *Engineering Magazine* for September.

might be permanently injured by the action of loads much smaller than those which the old theory would consider serious.

The elastic theory having been considered and practically accepted for metallic structures, it became a question how far it was applicable to those of masonry. In order to solve this, as well as to add to the stock of experimental data upon the general subject of arches of various materials, the Austrian Society of Engineers and Architects appointed, several years ago, a committee composed of some of its most eminent specialists to investigate experimentally the behaviour of large arches under known stresses, and to test the whole subject upon so large a scale as to furnish data of real practical value for future use in arch-design and construction. The report of this committee, published in the journal of the society and subsequently in a special reprint consisting of 131 folio pages and 27 large plates, is undoubtedly the most important publication on the subject of the arch which has ever been made. The technical details of the subject are too voluminous and mathematical to be given here, and for them the professional engineer must be referred to the original publication; but an account of the general nature of the tests and the results obtained are of so general interest and importance as to be worthy of general attention. The preliminary portion of the work consisted in experiments made upon small arches, such as are used in fireproof building between floor-beams and the like, and these need not be discussed here. The important tests were those made upon several large arches of different kinds.

Those in which we are interested were made upon four arches, each of 23 metres (75·4 feet) span, 4·6 metres (15·1 feet) rise, and 2 metres (6·56 feet) width. Three of these arches were of materials in general use, *i.e.* rubble, brick and concrete, while the fourth was of the so-called Monier construction, consisting of concrete in which is embedded a network of round iron rods to assist in resisting the tension stresses. The location of the experimental arches was well adapted for the purpose, being on the line of the Western Railway at the Purkersdorf station near Vienna.

Although the curves upon which the arches were constructed were arcs of circles, yet for so flat arches the circular arc differs so little from the equilibrium curve for uniform loading that the latter occupied practically the middle of the arching. The test, therefore, was made by loading one-half of the arch gradually, measuring the deflections very carefully at points along the entire curve, and watching carefully for the appearance of cracks or other symptoms of distress. This one-sided loading was intended to cause the distortion of the arch to a much greater extent than was likely to occur in practice; if the cracks appeared at the points indicated by the theory, the deductions were to be considered sustained.

The materials used were tested by sample beforehand, and the modulus of elasticity determined in each case, so that the theoretical and practical conditions could be compared.

Many ingenious and delicate devices were used for measuring the deformations of the arches at different points under increasing loads, as, under the elastic theory, the deformations should be proportional to the loads until the elastic limit is reached; the importance of exact measurements in this connection was, therefore, very great. The loads were applied at points prepared in the construction of the arches in the form of steps at equidistant points in the span, this form of loading giving a clearly-defined distribution at definite locations, and also corresponding to a satisfactory method of supporting the roadway in actual constructions.

As the method was the same for all the arches tested an account of one will serve for all. Taking the case of the rubble-stone arch, the load of the arch itself was gradually distributed, the depth of the key being 23·6 inches, and at the springings 43·3 inches, while the additional load was applied at six points equidistant from the crown to the springing. The test load was composed of rails piled upon the platforms above, and gradually allowed to descend upon the arch in determinate quantities, the measurements giving the corresponding deflections.

As the loads were applied, the deflections increased almost in direct proportion to the force applied, showing that the laws of elasticity hold good for masonry as well as for metallic structures, while, after the elastic limit was surpassed and cracks began to form, both the location of the cracks and the point of maximum deformation showed that the position of the equilibrium curve practically coincided with that demanded by the elastic theory. The cracks began to appear when the one-sided load reached about 500 lbs. per square foot, and in nearly every case they occur at those points furthest from the distorted line of pressure—that is, at the portions under greatest tension—and it was at these points that the arch finally failed when tested to destruction with a load of 660 lbs. per square foot.

Practically similar results were obtained with the other arches, the differences in strength and distortion being only those due to the difference in material, and the theory being sustained in all cases. In the report, which was jointly prepared by the twelve members of the committee, all the data are given

in detail, and the mathematical discussion is worked out in full, while graphical diagrams show clearly how the results of the tests may be applied to the design of future arches.

One of the most immediate results of these exhaustive and valuable experiments was the construction of the great arch over the Pruth at Jaremcze. This is a stone arch of 65 metres span by 17·9 metres rise, or 213 feet by 58·6 feet, and has therefore a greater span than any other railway arch in the world. The only arch exceeding it is the Cabin John Arch near Washington of 220 feet span, but that carries only an aqueduct and is therefore not subject to the action of moving trains. The Jaremcze arch was designed by Inspector Huss, directly upon the lines indicated by the results of the tests of the committee, and in its construction the distribution of the load was effected in a manner similar to that adopted in the tests. This fine arch, completed in 1894 at a cost of about 34,000 dols., was the first fruit of the result of the work of the committee, and it is probable that other great arches will be constructed on the same lines.

The report contains a design for a similar arch of 120 metres span (393 feet). In some particulars the proportions differ materially in the two arches from those called for by previous methods; the effect is artistically pleasing, while the strength and distribution of material are such as to conform fully to the requirements developed by the tests.

It is a matter for congratulation that the work of the Austrian Society of Engineers and Architects has practically solved the problem of the arch, and enabled both its theory and practice to be established upon a sound and fully-demonstrated basis.

TESSERÆ.

Inigo Jones as a Designer.

IF we take a critical survey of Jones's designs we discover first the sketch, the outline and the shadows; and in this he is only equal to his school. But by a consummate skill in assorting his parts he stamps his name upon the edifice. With the same cornice, architrave, balustrade, figures and pediment as others employ, a very different arrangement appears. If his front be short, we see this more particularly. He destroys the stiffness of outline by the detail. His decorations are sometimes sweeping and reclining in their form; and it was a desire to avoid the rigid line in ornament that taught him to break the tympanum for the introduction of a wreath or a shield. If the wings are raised (which with him is usual when the centre is much depressed and the main body of the building long), he seeks to relieve by a depression of form (very frequently) in the decoration. The architrave sometimes sweeps into width towards the base, as in the wing of Wilton House. He seldom employs one uniform unbroken balustrade in the middle part along the whole length, unless there has been a paucity of reliefs below. In Wilton House, too, we see this. If, however, the front be long and the design a mansion, the various parts assume the varied forms and, together with the detail, unite their effect; the various points of the building in this case assume an inclination in form as they soar up and encounter the sky. They exhibit no harshness in their outline, or very little. He seems to unite with Wren in opinion and taste, and to mould the figures into spheres and sweeps as they stand against the sky. It is this which regulates him even in the balustrade vases and globes that crown the cornice. It is something of this which directed a pediment on the wings of Wilton House, for it leads the eye in breadth as a balance to the loftiness of the wing and avoids the harshness of the horizontal. It may be admitted that this disrelish for harshness often led him into extravagance in composition and caused him to exhibit in his smaller studies a richness and exuberance more fitted for an interior. It may be admitted, too, that a certain want of severity in taste and coolness in adjustment led him to trespass beyond what his more careful rival Burlington dared to allow. Often he may appear omitting the necessary members from a cornice, omitting the frieze and introducing double plinths; still that richness of the artist, snatched from Italy, is a charm entirely his own.

Specific Style in Art.

In all the fine arts some external attraction, some element of beauty, is the vehicle of mental pleasure or moral interest, but in considering the special form or means of any one of the arts, as distinguished from the rest, the excellence of each will be found not to rise from the qualities which it possesses in common with its rivals, but from those qualities which are peculiar to itself. We thus comprehend why various schools have attained great celebrity in spite of certain defects. It is because their defects are generally such as other modes of expression could easily and better supply. Their excellences, on the contrary, are their own, and not to be attained except in the form of art proper to them. Such excellences constitute

what may be called specific style. Accordingly, it may always be assumed that pictures of acknowledged merit, of whatever school, owe their reputation to the display of qualities that belong to the art of painting. In histories of painting these merits are often attempted to be conveyed in words, and the mode in which language endeavours to give an equivalent for the impressions produced by a picture is at once an illustration of the above principles. The changes of time, of motion, the imagined interchange of speech, the comparison with things not present—all facts beyond the scope of a silent, stationary and immutable art—are resorted to without scruple in describing pictures, and yet the description does not, therefore, strike us as untrue. It will immediately be seen that the same liberty is allowable and necessary when representation enters into rivalry with description. The eye has its own poetry, and as the mute language of nature in its simultaneous effect (the indispensable condition of harmony) produces impressions which words restricted to mere succession can but imperfectly embody, so the finest qualities of the formative arts are those which language cannot adequately convey. On the same grounds it must be apparent that a servile attention to the letter of description, such as accuracy of historic details, exactness of costume, &c., are not essential in themselves, but are valuable only in proportion as they assist the purposes of the art or produce an effect on the imagination. This may sufficiently explain why an inattention to these points on the part of great painters (and poets, as compared with mere historians) has interfered so little with their reputation. In this instance, while the powers of painting are opposed to those of language generally, they are on the same principle distinguished in many respects from those of poetry, and in like manner, if we suppose a comparison with sculpture, or with any other imitative art, the strength of painting will still be found to consist in the attributes proper to itself. Of those attributes some may be more prominent in one school, some in another, but they are all valued in proportion as they are characteristic, because, in short, the results are unattainable in the same perfection by any other means.

The Walls of Athens.

About 481 B.C. the Athenians restored their dismantled walls, and also enclosed the Piræus. From political circumstances the works were very much hurried, the foundations were laid with stones of all sorts and sizes, some unwrought and just as they were brought up by the servers. Many pillars, too, from sepulchral monuments and other wrought stones were worked up in the building; for the boundary wall of the city was now far greater, being in every direction carried out, and for this reason it was that they urged on the work, employing alike whatever came to hand. It was Themistocles, too, who persuaded them to build the remaining walls of the Piræus (for this had been begun by him during the year of the archonship which he filled at Athens), thinking the place highly favourable, as having three natural ports, and that, as they had become a nautical people, it would much contribute to their obtaining naval power. Indeed, he first ventured to tell them they should apply to the sea, and then immediately assisted them in acquiring the empire of it. By his counsel it was that they built the wall of that thickness about Piræus; for two wains brought stone, passing by each other upon it, and going contrary ways. Within there was neither rubble nor clay, but the stones were large and hewn square, fitted together in building, and those on the outside bound together with stone and lead. The height, however, was only finished to about the half what was designed, for his intention was to effectually repel all hostile attacks both by the thickness and the loftiness of the walls, and he thought that thus a few, and those the least effective, persons would be sufficient to man it, and that the rest might embark on board the fleet; for he chiefly devoted his attention to the shipping, perceiving, it seems, that there was a readier access for the king's (Persia's) forces against them by sea than by land. For he judged that the Piræus would be more serviceable than the upper city, and often counselled the Athenians that if ever they should be foiled by land, they should descend thereto, and with the navy make head against all opponents.

Freedom in Architecture.

Nothing can be more opposed to every legitimate principle of art and æsthetics than the attempt to reduce the different orders to so many express and immutably fixed types. The consistency so aimed at is attended with almost the worst species of inconsistency, because it totally excludes such modification as may be most suitable for the particular case. It is time for us to get rid of all the mechanical quackery to which we have so long submitted, and which has reduced architecture as generally practised to little better than a mere handicraft trade—to copying certain individual parts met with in former styles of the art without any regard either to the genius of the

styles themselves or to the circumstances of the building required. What puerile trifling it is to affect scrupulous nicety as to the express shape and proportion of every little detail belonging to columns which are to be stuck up by way of portico before a dowdy house or other building, which is thereby only rendered a grotesque absurdity. In most other matters people think of attending a little to consistency and common sense, or should they fail to do so they must submit to the derision of their neighbours. But in architecture the most ridiculous incongruities and *disparates* are tolerated—tolerated, they are even applauded, and *bêtises* that would hardly be endured in the preparations for a temporary fête may be perpetrated with impunity in buildings intended to be permanent.

GENERAL.

Mr. Pearson, R.A., has been invited to report on the restoration of the ruinous parish church of Mundesley, Norfolk.

The Society of Miniaturists will hold their next exhibition at the Grafton Galleries about the middle of October.

The Halifax Town Council have accepted the design marked "Victoria," and Messrs. George Buckley & Son, Halifax, the authors, are now instructed to prepare working drawings, specifications and bills of quantities, and obtain tenders for carrying out the various works required in connection with the erection of a police-station and court-house, at an estimated cost of 11,600*l.*, the buildings to be on the old infirmary site.

The Late Miss Gibson, of Durham, has bequeathed 300*l.* to Durham University to found a scholarship which is to be competed for triennially, the candidates having to write an essay on British archaeology or local history. Miss Gibson bequeaths an oil-painting by Romney to the National Portrait Gallery, and leaves a substantial sum for the erection of a stained-glass window in Durham Cathedral.

The Norwich Town Council have increased the salary of Mr. A. E. Collins, city engineer, architect and surveyor, from 600*l.* to 800*l.* per annum.

Mr. Milo Griffith, the Welsh sculptor, died at his house in Chelsea on the 9th inst. The statues of John Batchelor at Cardiff and Sir Hugh Owen at Carnarvon are his work; but his countrymen did not award him the patronage he merited.

The Late James Christie, of Regent Street, has bequeathed to Sir John Gilbert, R.A., or, if he should not be living, to the National Portrait Gallery, the portrait of Sir John, painted by himself, and presented by him to the testator. His pictures, prints and other works of art are bequeathed to the Rev. J. H. Christie, of the Brompton Oratory.

The Hawick Archaeological Society have resolved to erect a memorial-stone in the cottage at Hawick in which Robert Paterson, the prototype of Sir Walter Scott's "Old Mortality," was born. Paterson, who spent many years of his life repairing the decaying tombstones of Covenanters, died at Bankend in 1801, aged eighty-eight years.

The Local Government Board have decided to issue an order authorising the Metropolitan Asylums Board to purchase a plot of land on the Victoria Embankment from the Corporation of the City of London, for the purpose of erecting new offices upon it. The cost of the site is not to exceed 53,000*l.*

Birdforth Church, which dates from the fifteenth century, and was originally built as a wayside chapel, has been restored. The original building was of brick, surrounded at the western end by a turret, on which was placed an old wooden structure similar to the one which graced the old church at Scawton, on the Hambleton Plain. The restoration has been effected at the expense of Lord Dawnay. The old building has been reroofed with French tiles, and the pigeon-cote turret has been rebuilt with clamp bricks. The interior has been refloored and resealed, and the windows reglazed.

The Architecture, Building Construction and Modern Practice Classes, King's College, will open on October 4, under Professor Banister Fletcher, Mr. Banister F. Fletcher, lecturer, Mr. Phillips Fletcher, assistant lecturer, Mr. James Bartlett, demonstrator, and Mr. Banister F. Fletcher, studio instructor. A course of about thirty lectures will be given on Monday evenings from 7 to 8 P.M. Opening lecture, October 4. The lectures will comprise the subjects in which candidates are examined at the Royal Institute of British Architects' examinations for building surveyors, which examinations take place in April and October in each year; the examination for membership of the Society of Architects; the subjects in which candidates are examined at Carpenters' Hall in June in each year; also subjects required in the examinations at the City and Guilds Institute and the Science and Art Department; and the examination for sanitary inspectors in sanitary building construction held at Carpenters' Hall.

The Architect.

THE WEEK.

It is proposed to hold an exhibition of Christian art in Paris during the year 1900. It cannot form a part of the international exhibition, for after consideration the authorities decided that space could not be assigned for a special section, for if one were tolerated many similar applications would be sure to follow. The project has been initiated by the Prince DE LA ROCCA, and he has been enabled to obtain the aid of a committee consisting of thirteen cardinals, 300 bishops and a great number of other notabilities. The Italian Government have set aside all prejudices and will aid in promoting an exhibition which is likely to bring profit to Italy. There will be subdivisions to represent the art of different countries. Great Britain is not likely to require much space, for although enormous sums are raised every year for vestments, altar-plate, ornaments, pictures, &c., they are expended on foreign products which are generally devoid of the qualities which constitute art. The amount of money exported from Ireland if expended on Irish examples would do much to relieve poverty. The ecclesiastics are not absentees, but they imitate them in expending all the sums they can obtain for the benefit of strangers. Meanwhile, in the interest of good taste it would be an advantage if an exceptionally high import duty were imposed on foreign ecclesiastical properties.

NEITHER civil engineers nor contractors for engineering works are much given to value anything for its beauty. Sir WILLIAM ARROL, who is both engineer and contractor, should therefore be doubly indifferent to form. Yet we find him after the opening of the New North Bridge in Edinburgh advising the Corporation to undertake a costly work solely because it would increase the amenity of the city. All visitors to Edinburgh remember the gas works which are found in the valley near the new bridge. They do not improve the landscape, and they will look more out of place when the improvements to which the reconstruction will give rise are undertaken. Sir WILLIAM ARROL advised the removal of the works elsewhere, and also that only picturesque houses should be permitted to appear on the site. Sooner or later the change will have to be made, and we hope Sir WILLIAM ARROL's excellent speech will expedite the determination of the Town Council to deal with the problem.

QUARRY BANK, in Staffordshire, has a population of about 7,000, but at the present time it is not a desirable place to seek an abode. There are coal mines underneath, and as the coal is abstracted the buildings subside, being more or less shattered in the process. Lord DUDLEY, the owner, is under no restriction about his workings, and incurs no liability for damages to houses. It was possible at one time for the Town Council or individuals to purchase the minerals from his lordship, which would remove the cause of all the subsidences; but as the opportunity was neglected, it is now too late for complaints. Yet it is not pleasant to contemplate streets of dilapidated houses and to see shoring in progress at every turn in Quarry Bank. It is calculated that the underground operations will require a further period of six months; and during that time subsidences and other dangers must be expected. Lord DUDLEY has given a sum of money to aid in the reparation of some of the houses, but it seems an useless expense to pay for work which at any moment may be rendered useless.

THE Local Government Board appear to have resolved that every petty authority if it is to be responsible for the carrying out the by-laws within the boundaries, is also to have absolute authority. That would appear to be the conclusion to be derived from the conflict of authorities in Blandford. The Town Council as urban authority gave one of their members power to replace an ordinary shop window

with a bow window projecting about 1½ foot over the public pavement, but in line with the shop windows on either side. The County Council, as contributors towards the maintenance of the highway, requested that the projection should be removed on the ground that it was an encroachment on the footway. The Town Council refused to acknowledge any power of the County Council in the matter, whereupon 31%, a year's moiety of the grant for the highway in question, was withheld by the County Council. The Local Government Board were appealed to, and after holding an inquiry supported the Town Council by ordering the county authority to pay the 31%, with 13% as the costs of the inquiry. There is so much difficulty in obtaining sanction for bow windows or other projections that all architects will be disposed to side with the Blandford Council. At the same time it would be well to know why the action of the County Council was disapproved, for it was inspired by experience. We hope the Local Government Board will not allow unlimited opportunities for the discussion of the question, but will issue a statement announcing when a county council can interfere with the action of an urban council or other subordinate authority.

ANOTHER prehistoric canoe has been found in Ireland. In this case the place which yielded the relic was Lough Elia, or the Lake of Swans, near Strokestown, in the county Roscommon. The canoe was embedded in the mud below the lake, and not far from the remains of a crannog. The canoe is 33 feet 6 inches long and 2 feet 10 inches wide near the stern, and tapers to about 1 foot 9 inches in width at the bow. It presents the unusual and interesting peculiarity of having been repaired by the addition of slabs of oak where the sides had become defective. These slabs are cut so as to fit closely to the sound portions of the sides, and were attached by large numbers of broad-headed nails of iron. It is not, therefore, impossible that the period of usefulness of this canoe may have been prolonged from the Bronze into the Iron age. In the lake was also discovered a bronze basin or cauldron over 19 inches wide and 7 inches deep. It weighs about 3½ lbs., and was wrought with the hammer from one piece of metal. Both relics belong to Mr. G. A. P. KELLY, M.A., of Cloonglasny-more, Strokestown.

THE Deputy-keeper of the Public Records in his last report announces that the new block of the Public Record Office facing Chancery Lane having been completed in 1895, as stated in his last report, the House of Commons voted a sum of 20,000*l.* for the financial year 1896-97 towards the erection of another block, which will connect it with the portion erected between 1850 and 1871. The cost of this fourth instalment of the General Repository of Records is estimated at 50,000*l.* The site having been cleared by the demolition of Rolls House and Rolls Chapel, the work was begun in the month of February 1896. Among the work done during the year, the list of rentals and surveys, so far as it deals with documents formerly scattered among the Miscellanea of the Exchequer, has been completed in manuscript and placed in the Search Room. The researches in foreign archives are in progress. Mr. BLISS, who is at the Vatican, has completed the Calendar of Petitions to the Pope between the years 1342 and 1419. The text of the Calendar of Papal Letters between the years 1342 and 1362 was also completed at press. Some materials for another volume of his Calendar of Papal Letters were collected. Mr. HORATIO F. BROWN has continued his researches in the Venetian archives. By the end of 1896 nineteen sheets of a new volume of his Calendar of documents and entries relating to English affairs had been passed for press. This, when completed, will bring the work down to the death of Queen ELIZABETH. Don PASCUAL DE GAYANGOS has prepared twenty-four sheets of a new volume of his Calendar, relating to Spain, Brussels and Vienna, beginning with the year 1544. Major MARTIN A. S. HUME has prepared the text of another volume of his Calendar. Mr. J. H. ROUND has passed for press four sheets of a Calendar of early documents in France relating to England.

FRENCH CRITICISM OF MR. RUSKIN.

BY A CORRESPONDENT.

THE first article of any importance upon Mr. RUSKIN which we can remember as appearing in French periodicals was one in the *Revue des Deux Mondes* for July 1, 1860. It was entitled "Une Nouvelle Théorie de l'Art en Angleterre." On August 15, 1861, another article was printed with the title "De l'Influence de la Littérature sur les Beaux-Arts." Both were by M. J. MILSAND. The *Revue* about that time was endeavouring to put forth more exact notions about English ways than were current in France. The long series of articles by M. ALPHONSE ESQUIROS, those by M. TAINÉ, M. E.-D. FORGUES, M. CLARIGNY, M. DUPONT-WHITE, M. LAUGEL, M. E. MONTÉGUT and others are evidence of a desire to arrive at the truth, which is most creditable to a periodical that is deservedly esteemed throughout the world. In the case of Mr. RUSKIN there was more than usual courage shown. From the peculiarity of their publication his books were soon classed in England as curiosities, and care was taken by purchasers to keep the pages uncut. That was not favourable to a dissemination of Mr. RUSKIN's opinions. The volumes were not translated into French, and when M. MILSAND assumed the office of interpreter he could not rely on his readers having an elementary knowledge of the subject. In England we have been familiar with Mr. RUSKIN's apparent inconsistencies, but they were treated lightly among us, for we knew that a man who endeavoured to judge of things from many points of view, and who put himself in the place of a variety of men living in different times and places, and tried to see things as they did, could not be expected to run always in one groove. Hence it was, no doubt, that M. MILSAND, in his titles at least, avoided the temptation to make his articles biographical or individualistic, and the English writer became almost impersonal and secondary to the theories he devised.

If a subject could have a tongue it would ask of every critic, like old GRAHAM of Netherby of young LOCHINVAR, "O come ye in peace here, or come ye in war?" and in a good many cases the answer would be indecisive. M. MILSAND said he came forth as "un pauvre critique" in the defence of painters and other artists. Such a position recalls the schoolboys who will allow nobody to abuse their fags but themselves. But what M. MILSAND really maintains is that art has to obey certain definite laws which arise out of its conditions and no others. To insist, as Mr. RUSKIN was supposed to have done, on a faithful observance by the painters of laws which belong to literature would be to turn their art into a state of confusion, for its own natural laws would be neglected, whilst the newly-imposed laws would not be obeyed. But in saying so much Mr. RUSKIN was considered as only the latest and most revolutionary of the theorists who have taken upon themselves the guidance of artists. M. MILSAND believes that every true artist should be a lawgiver to himself, and the palmy days of art were those in which artists dwelt apart from the world as in a sanctuary, communing with their own thoughts and respecting the traditions of their predecessors in the school, days when one could say to a Pope *procul esto* and bar his admission to the workshop. But when by degrees the public got the upper hand and insisted on being gratified, and plausible speakers and writers instructed the public about what was indispensable for their gratification, which they did not know before, it followed that the artist was compelled to sacrifice his art and to become like the other performers who entertain votaries of pleasure. According to M. MILSAND's conclusions, Mr. RUSKIN is almost as complete an expression as can be found of the good and the evil that literary influence can accomplish in the plastic arts. The good is a profound sentiment of the moral conditions which the artist is bound to fulfil, but the evil is the turning of pictures and sculptures into books, and making them correspond with the ideas of the romance writer, the historian, the botanist, the geologist and the anatomist. Farewell to the magic of art, exclaims M. MILSAND, farewell to the emotions it alone can excite, if it must play the rôle of science or ethics, or even poetry, and if the painter and sculptor must abandon the aptitudes and sensibility which are their peculiar gifts in order to pose as thinkers or as poets. We can perceive, then, from the

starting that M. MILSAND is endowed with the logical keenness which is characteristic of the French race when it deals with words. He will have no overlapping of things, and although schools of aestheticians maintained for centuries that all the arts have common principles, he insists that the plastic arts and the literary arts cannot be confounded without risk to both.

But what is the science that is known as æsthetics? In M. MILSAND's explanation of it Mr. RUSKIN would be likely to find something which he would approve, but a great deal which he would hold to be false. When WORDSWORTH says, "Heaven is about us in our infancy," and accompanies us with splendid visions until manhood perceives them fade into the light of common day, and "nothing can bring back the hour of splendour in the grass, of glory in the flower," he was in a measure anticipating M. MILSAND. The more one investigates the more one discovers, he says, that æsthetics has against it all the laws of the universe and of human nature. The logician can find laws of thought within himself, but the æsthetician, on the contrary, is a man of reflection who tries to comprehend varieties of production that come from a mental condition of which no trace remains when a man becomes competent to reflect. What has happened in history corresponds with individual life. When in Greece the national genius had expressed itself in art, the rhetoricians and scholiasts appeared to lay down the laws of beauty. In modern Europe a similar race was found after SHAKESPEARE and MICHEL ANGELO had performed their work, and there was no longer original inspiration. In fact, says M. MILSAND, the science of æsthetics is a putrid generation, a decomposition of the imagination.

Apparently, what M. MILSAND aims at teaching is that the visions, thoughts and emotions which belong to the creative artist are not to be acquired from books. It is difficult to define the period when they arrive to the artist who has had experience of their power, and it is therefore allowable to suppose he possessed them in childhood, although in an elementary state. WORDSWORTH, from his own account, was an embryo poet when he was a child of ten:—

I held unconscious intercourse with beauty
Old as creation, drinking in a pure
Organic pleasure from the silver wreaths
Of curling mist, or from the level plain
Of waters coloured by impending clouds.

It is easy to imagine that a boy who was destined to be an artist would be still more impressed with such scenes. Mr. RUSKIN's father believed it was his duty to bring his son amidst scenes which would act upon a sensitive mind, and accordingly the boy was acquainted almost from his infancy with the most beautiful scenery that was to be found in England, France and Switzerland. How he felt before the scenes is recorded in descriptions that were never surpassed, and it is only natural for Mr. RUSKIN to expect that the thoughts which arose in his mind in the English lake district or amidst the Alps should be as easily excited by a painted landscape.

The early acquaintance with landscapes of all varieties has, however, caused a confusion of ideas with Mr. RUSKIN. The impressions he received in the Alps and Italy were revived by TURNER's pictures, and he confounded the secondary with the original influence. TURNER, we know, grumbled when he found meanings were read into his pictures which he had never contemplated, and which they were still incapable of suggesting to him, in spite of the eloquence of his votary. But it is the old story. The eye sees what it brings the power to see, and as the primrose by the river's brim, the daffodils and other wild flowers excited emotions in WORDSWORTH which words could not express, so certain paintings and drawings have had the power of reviving associations in Mr. RUSKIN's mind of the most delightful kind, while before others he was as indifferent as WORDSWORTH would be with the delicate plants of a conservatory. His whole advice to painters might be summed up in a few words; it was simply, "Paint me pictures which will affect me like the perspectives of TURNER, the continental towns of PROUT, the birds' nests and primroses of WILLIAM HUNT. I am unmoved before RAPHAEL's greatest works, but I cannot resist anything which recalls Caterham or

Chamouni." This conversion of a personal need into an universal requirement may be said to be a peculiarity of the English poetic nature. DANTE is the only exception abroad. But no men are so little affected by it as the French, and on that account we believe M. MILSAND is not entirely correct in all he says about Mr. RUSKIN's endeavour to make pictures become books. It arises from what the Elizabethans would call a fine madness, and it is hardly to be subjected to the tests of modern logic. But the effect on art has not been advantageous. The painters who endeavoured to please Mr. RUSKIN have not produced masterpieces.

But M. MILSAND is not indifferent to the services which Mr. RUSKIN has rendered to art. He maintains it was the English writer who swept away the old superstition of the beau-ideal, a theory which sterilised the imagination by turning it from nature. To him also is owing the overthrow of the no less dangerous doctrine that in the grand style there should be no sign of anything that was peculiar or individual. He has also successfully fought against the belief that the artist was to consider himself as a workman and a master of processes, and has demonstrated that no one can communicate an emotion who has not felt it, for the great masters have succeeded because they have reproduced themselves in their works. It is remarkable to find a French critic attributing so much power to Mr. RUSKIN in 1860, and one can hardly believe that M. MILSAND described effects which were to be seen in French ateliers. But there is no use, he says, in endeavouring to judge of Mr. RUSKIN by occasional expressions of his thoughts. In his writings, says M. MILSAND, we find an intense and profoundly just sentiment of an art that is living and large as nature and man, and which sentiment could only have its source in an universal sympathy, in a genius for loving and a force which compels us to yield to the beauty of whatever is described. Even under the endeavour to confound the domain of the painter with that of the writer we find a desire to animate art by attaching it to the movements of our thoughts and the force of our moral nature, a profound perception of the influence that the good and bad qualities of character can exercise over the works of man's hand, whether he is painter or carpenter. In fact, M. MILSAND believes that among Mr. RUSKIN's ideas few have so much chance of endurance as those relating to the ethics of art. It is as a moralist especially he values him, and he considers that much is to be gained by men of all nations who will attend to what he says and endeavour to paint and carve, not to suit the fashion of the moment, but to express the beautiful and the true according as they appear to the artist's own consciousness.

(To be continued.)

ELECTRIC TRAMWAYS.

By F. J. WARDEN-STEVENS, A.M.I.E.E.

(Continued from page 180.)

THE double-trolley system was introduced to obviate the difficulties of the earthed return; as its name indicates, it consists of two wires, on which run two trolleys. The current is led to the car by one trolley and back to the station by the other. This method enables a high insulation to be kept up, and it considerably reduces the danger of a shock due to falling wires, as only a comparatively weak shock is possible if the insulation is good. The great difficulty is at the crossings, and the appearance of the wires is very objectionable. Owing to the introduction of electric welding and improved rail bonds, this system is never erected now, as it is more expensive and unsightly, while it is very little better than the ordinary single trolley.

Third Rail System.—This is practically the trolley system, except that the conductor is on the ground level instead of overhead. This system is only applicable to a railway, *i.e.* a line which is enclosed from the public, as, of course, it is an impossibility to allow traffic over the conductors, which are bare. The conductor is usually supported on insulators, sometimes wood and glass, and sometimes wood treated with wax. The conductor is sometimes stretched at intervals by means of weights and

levers. The system of making contact is either by a slipper or a trolley wheel, as in the overhead system. This method of line construction is far and away the cheapest when it can be adopted.

Conduit Systems.—There are many systems which come under this heading, but there are few which have been used practically. The idea of the system is to place the conductor in a conduit, in a similar way to the mechanical cable system. The conduit is in various methods, built of cement, concrete, iron, &c. In some cases one conductor only is used, the return being by the rails; in others both conductors are insulated, these being by far the greater number. The conductors are usually fixed to the conduit by means of insulators, the contact being usually a "rubbing" one, which collects the current from the conductors and delivers it to the car. The number of conduit systems are almost innumerable, and they are all expensive. The conditions under which they are useful are not very extended, being chiefly confined to city thoroughfares where overhead wires are impossible or prohibited. It is, of course, necessary to have a slot in the road and a ploughpiece carrying the contacts. If anything goes wrong with the conductors it is almost impossible to remedy matters without taking up the roadway. The chief cause of trouble is, however, that of electrolysis. The conduit, as a rule, becomes the sewer for surface-water in heavy storms; mud falls down and electrolysis is caused by the leakage. With any successful conduit an elaborate drainage arrangement must be provided, and even then there is the difficulty of mud, stones, &c. The difficulty of electrolysis has not yet been overcome in a satisfactory manner, while want of accessibility must always be urged against it. As before mentioned, the chief use for this system is in situations where the overhead trolley has been prohibited, where the streets are narrow and overhead wires would be a serious obstruction, and where the ordinary traffic is very heavy. In the latter case, the conduit and the accumulator systems clash, and are in competition unless the district is hilly, in which case the conduit has the advantage.

Closed Conduit Systems.—These systems are all designed with the object of removing the slot in the roadway and of closing the conduit. They are thus sometimes referred to as "surface-rail" systems. The slot in the road being dispensed with, it becomes necessary to use some surface contact. This is usually done by providing surface studs, and in some cases by utilising sectional rails for the purpose. The whole of the ingenuity of inventors has been expended on connecting and disconnecting these rails or studs, so that they shall be switched on when under the car and off when the car leaves them behind. The usual means of making and breaking these contacts is to have a magnet on the car which attracts an armature in the closed conduit, which makes the stud "live" until the car has passed over, when the armature of course falls again, breaking contact.

The use of studs is much better than utilising the rails, as there is less liability to obtain live metal in other places than the car. The conductors in the conduit are insulated, thus the difficulty of electrolysis is overcome; the studs are usually insulated, in some cases by being sunk in porcelain blocks which are again protected by an iron shoe. At any rate, there is no great need for perfect insulation, as the pressure is only on the stud for a very short time. The current is collected from the studs, when used, by means of a trailing bar which makes contact with them. The studs are raised a little above the roadway, thus enabling the bar to keep in contact. Before one stud goes out of contact the next contact is made, so there is no discontinuity. The car is, of course, of the usual construction, the only difference being that the trolley is absent. There is no doubt that, speaking generally, these systems are preferable to the open conduit, but, of course, there are many details to be perfected before they can rank in reliability with the overhead trolley.

The great advantages of this system over the open conduit are as follows:—It is impossible for mud or water to cause trouble, there is no danger of electric shock to horses or the public if properly designed, all cables are insulated throughout, so there is no possibility of electrolysis. Surface conductors are only "live" for a few moments, so the effect of electrolysis on them is insignificant, there is no slot in the roadway, and a source of danger to pedestrians

and cyclists is removed. The first cost and cost of maintenance is lower, or should be. In some systems there is no conduit at all, only the surface contacts, the cables being laid in the ground adjacent to the rails. There is a great future before these surface contact systems in large towns where there is heavy traffic, and also for the city end of suburban lines, as the same car can be worked on both systems, the change being made when the traffic becomes dense, or at the limit inside which overhead conductors are not allowed. The trolley can be clamped, and the surface contacts brought into action without stopping the car.

Various new Systems.—A system which is very like the surface contact is about to be introduced. In this system the overhead wires are abandoned. The necessary contact between a fixed conductor and the car is obtained by having a contact wire or ribbon stretched along as great a length of the car as possible. This conductor may be as much as 50 feet long, varying, of course, with the length of the car.

The contact wire or ribbon upon the car makes a rubbing contact on its upper surface with contact pieces or trolleys suspended transversely to the track from the arms of ordinary street trolley poles, so as to lift and swing slightly in the direction of the car movement, when the travelling car contact comes underneath and presses upwards. When short distances are permissible between the street poles, say 18 or 20 yards, the travelling car will make contact continually, as it will come into contact with a second pole before leaving the first one. When a distance of say 40 yards is the minimum allowed between the poles, a contact stud or plate is placed on the track, similar to those already mentioned. This is placed midway between the poles. It is switched on by the action of an arm fixed near the rear end of the conductor on the car just before it leaves the pole contact, and off by a similar arm fixed to the front of the car just after contact has been made with the next pole. The current is of course conveyed to the poles by means of insulated cables laid in the ground. It is anticipated that with this system the cost will be only 25 per cent. in excess of that for the simple trolley, while the objectionable overhead conductor will be dispensed with. The poles can be used for street lighting, as they are at about the correct distance apart. The stay-wires at curves, necessary for the ordinary system, can be dispensed with, and also there is less complication at crossings. It is of course premature to pass any opinion on this system till it has been tried practically.

There is another system which involves the use of an entirely new principle in electric traction, but no really practical trials have yet been made. This system involves the use of alternating currents, and is virtually a transformer, the fixed part of which is in the roadway and the movable part on the car. The fixed part consists of a trough-shaped iron circuit buried in the middle of the track; a thick copper conductor runs the length of the track, and returns underneath the iron, thus forming one turn of wire on the transformer with half the magnetic circuit. The rest of the magnetic circuit is on the car, with windings. This circuit consists of a mass of iron approaching the ground, of a similar shape to the buried iron. If alternating currents are passed through the buried conductor, currents will be induced in the winding on the car without any actual passage of current between the road and the car, the energy being transmitted through the air gap by means of magnetism.

(To be continued.)

HOTEL DE VILLE, ANTWERP.

EXAMPLES of Renaissance architecture appeared in Belgium about the same time as in France, that is, at the close of the fifteenth century, but they were more slow in attaining popularity. The consular house of the Biscayens in Bruges, which, according to GAILLIARD, was constructed in 1495, was the first experiment in the new style. It is supposed to have been designed by some Italian or Spanish architect. Then followed a period of hesitation, and it was not until after an interim of about thirty years that signs of the influence of the Renaissance were again observed in

examples of interior decoration and ecclesiastical sculpture. The fine chimneypiece of the Franc de Bruges was executed in 1529 by a local sculptor, who was manifestly an adept in the style. One of the chimneypieces in the Hôtel de Ville of Oudenarde and the tabernacles in the churches at Leau and Tongerlo were of that time. It is not until 1537 that we can find another example of a building that is true Renaissance, viz. the old registry at Bruges. The publication of a translation in Flemish of VITRUVIUS in 1549, and of five books of SERLIO between 1539 and 1553, by PIERRE COECK, a painter and architect who was patronised by CHARLES V., gave an impulse to the foreign mode. The entry of PHILIP—the heir to the throne—into Antwerp gave occasion for much display. It is remarkable that not one of the triumphal arches erected on the occasion was in the old Flemish style.

Although the employment of the later and transformed Gothic for civil buildings soon ceased to be common, it continued to be in favour for church work. The Renaissance style is found in such buildings as the Hôtel de Granville in Brussels, the College Vandale in Louvain, the hôtel de ville and some of the guild halls in Antwerp, &c. Among the architects who were most patronised were JEAN DE BREUCK, HENRY DE PAS, and FLORIS or DE VRIENDT. The most important work of the period was the Hôtel de Ville in Antwerp, which was constructed between 1564 and 1580, from the designs of CORNELIUS DE VRIENDT. It has a length to the public square of 305 feet. FERGUSSON found fault with the treatment of the central part, and especially with the unmeaning obelisks. But he adds:—"Notwithstanding this, there are few more successful designs of its class. It is free from all the extravagances which disfigure structures of its kind and age, and equally free, on the other hand, from the affectation of grandeur which so often deforms later buildings. Each storey here is complete in itself, and there is not a single ornamental feature applied which is either more or less than it pretends to be. In the present state of feeling on this subject it would be the height of rashness to compare this town-hall with its Mediæval rivals. But take away their towers, and place them where they can be equally well seen, and the Antwerp town hall will stand the comparison as well as any other building of its age or class. Except to the extent to which the design of any one man must be inferior to that of many, and that a foreign style must be more difficult than a native one, it meets most of the requirements of good and truthful architecture." The building was hardly completed when the civil commotions burst out, and not only interfered with the erection of new buildings, but caused the destruction of several ancient examples of architecture.

SANITATION AND CONSTRUCTION.

THE presidential address in the section of Engineering and architecture at the Sanitary Congress, Leeds, was delivered by Mr. Lewis Angell. In the course of it he said that the most striking feature of the Victorian era had been the development of the practical and useful. The predominating feature of the engineering of the ancients—bridges, aqueducts, pyramids—was massiveness, but through the intermediate ages, excepting in now obsolete fortifications, scientific engineering made no advance. It was not until the reign of Victoria that the profession of the civil engineer came into existence, and they had now arrived at a condition of *nil admirari*, and become as gods "directing the great sources of power in nature for the use and convenience of man." Engineering and architecture represented the constructive side of sanitary science. One branch of engineering had revolutionised war, but the works and objects of the sanitary engineer were not for the destruction, but the preservation of life and the promotion of health and comfort. If the millions expended in war had been devoted to life-preserving sanitation, what a different result would history have had to record. The science and the laws of sanitation were now well-known and established, and all he could hope was to drive home old-established truths by repeating line upon line and precept upon precept. Although the sanitary branch of engineering was a modern subject, they found very early records of sewers. Historically it was usual to quote Moses as the first practical sanitarian. The first "destructor" they read of was the Gehenna, or hell-fire, outside Jerusalem, where the refuse of the city was burnt. Destructors of a different type might be seen outside Leeds. England really originated sanitary work, but free and demo-

cratic America, having less sentimental notions respecting the liberty of the subject, had in many ways been in advance in the control of such matters. In New York and other States that great offender, the plumber, had for a long time been placed under official inspection. The President then recapitulated the succession of Sanitary Acts, which were at first, he said, only of a tentative and permissive character. Upon

the general engineering principles of town drainage, engineers were in the main agreed. The English water-carriage system was accepted as the cheapest, most efficient and least objectionable, and was universally extending, and would ultimately extend, to every civilised town in the world. The history of sewage revealed erratic procedure. Sewage was thirty years ago declared to be a "mine of wealth" if applied to land.

HOTEL DE VILLE, ANTWERP.

Sewage farms had had their day, however, and chemists, patentees and stockjobbers had failed. The question had now taken a new and interesting biological aspect. They were harking back to first principles, to the engineer's tanks and the resurrection of the microbe hitherto killed by the chemist with his patents and reagents. Probabilities indicated that microbes worked for good and evil, and that the good would prevail; that the purification of sewage would be effected by living organisms. Referring in detail to sewer ventilation, the President declared himself in favour of free and open ventilation. The cardinal conditions of health—pure air, pure water and unpolluted earth, with the accessories of wholesome food, proper clothing and suitable houses, the necessities of life—comprised the whole gospel of sanitation. In our own habitations there should be ample means of ventilation in all living-rooms, no connection between the dietetic water-supply and the drains, no connections with the sewer except for the discharge of sewage, that the drains should be trapped outside and freely ventilated, and that all discharges from cisterns, baths, &c., should be in the open air. The President commented on the decision of the Queen's Bench, by which the term public sewer applied to every description of drain and sewer except drains used for the drainage of one building only, or premises within the same curtilage. The Lord Chief Justice might well have said that the condition of the sewer laws was a scandal. Several recent attempts had been made to put the law on a more equitable basis, but the bills had been invariably blocked in the interests of property-owners. There was, however, a Nemesis in all this. The local authorities of the past would not provide the small staff of inspectors necessary for the proper supervision of buildings and house drainage, and unprincipled owners and "jerry" builders could on their own premises do very much as they pleased. The local authorities had now to provide not only a large staff to discover the defects of the past, but, at great cost, to remedy the bad work, which could have been prevented by proper supervision. The housing of the working classes was a prominent feature in sanitation. Whether this should be accomplished by flats or by workmen's trains was a matter for serious consideration. Much good had been effected in the Metropolis by the clearance of unhealthy slums and the substitution of piles of tenements, but it was questionable whether it was desirable to concentrate the working population on so limited a space, with only street gutters for the children's playgrounds. With the facilities now given by the very cheap workmen's trains and trams, it would be infinitely better to distribute the population. The requirements of the model by-laws of an open space—relatively small though it be—at the rear of houses, and a specified width of roadway in front, precluded the repetition of the old courts, alleys, slums and rookeries, as also the very objectionable back-to-back houses, which, unfortunately, continued to exist in many towns which could be named. Local government was a grand principle—in theory—but the procedure of some local governors, headed in newspapers as "disgraceful scenes," "scandals," "personalities" and "rowdism," led cynics to inquire whether local government was not, in practice, a fraud. Unfortunately, excepting in the great cities, local affairs were not only too frequently avoided by those most fitted to take part therein, but a very large portion of the population took no interest whatever in matters affecting their welfare, as evidenced by the scanty polling at local elections; but when an epidemic scare occurred, people who at other times are utterly careless of their local institutions or representation break out in hysterical denunciations of local management. After referring to the disposal of storm-water and the proper dimensions of house-drains, he said:—Sanitary principles, they were told, if carried to their logical conclusion would prohibit carpets, tapestry, curtains, architectural mouldings and reliefs—anything, in fact, which could harbour dust and dirt in houses; walls should be smooth, polished and without angles. In food people must so study what to eat, drink and avoid, and by an all-round anxiety to preserve health render life not worth living. There was the happy medium in all things which wisdom dictated. Small local practitioners took up sanitary shibboleths, and dogmatically ascribed to sewers, gullies or ventilators illnesses for which they could not otherwise account. Even those from whom they expected more science frequently gave their dicta without taking the trouble to investigate. Typhoid and diphtheria were generally ascribed to sewers and drains, but nearly every large outbreak of enteric fever had, upon careful scientific investigation, been distinctly traced to contaminated milk or water, and not infrequently to shell-fish, while diphtheria had been ascribed to personal contamination in schools. The municipal engineer should have had a liberal education to safeguard him against the narrow motives and influences by which he was surrounded. He should be something more than a sanitary "expert." He should have practical experience in general engineering. At present the office of engineer was open to any brass-plate man who could obtain responsible official positions upon the mere testimonials or votes of good-natured friends. The Sanitary

Institute, as also the Association of Municipal Engineers, had established examinations to test the knowledge of aspirants for public offices. Such examinations might not be an absolute proof of general fitness, but as an examiner he said they afforded *prima facie* evidence that the candidates who passed were not mere quacks, and local authorities would do well to require diplomas or certificates before making an appointment. It should not be competent for anyone not holding a qualifying certificate from some recognised examining board to present himself as a candidate for any of the higher municipal offices. Subject to such evidence of qualification, local authorities might have the selection and appointment of such officers, which appointment, subject to good behaviour, should be as permanent as in the Civil Service, carrying with it superannuation. They had long advocated that the skilled and responsible municipal service of the country, offices created by Parliament, should be allied to the Civil Service on a system somewhat analogous to the county surveyorships of Ireland, which should include the medical officer and the engineer, extending also so far as he acts independently to the chief sanitary inspector. A new and unexpected force was already making for sanitation, in the shape of a demand from the working classes. Labour representatives on local authorities were eager in promoting sanitary inspection, perfect drainage, improved dwellings, public baths, recreation-grounds, &c., to the great advantage of the working classes. Sanitary works and a sanitary staff, of course, meant rates, but rates for preventive sanitary measures are paid grudgingly. As a matter of social economics, the value of health, comfort and prosperity was to be credited as against the loss of labour, waste of capital and cost to the nation consequent upon sickness and pauperism. Without health all other advantages were diminished or lost, therefore the conditions of health, so far as they were under control, should be a subject of the education of the people; the elements of hygiene should be taught in Board schools, in high schools and in colleges, and illustrated by practical object-lessons supplied by landlords.

Mr. Lemon (Southport) moved a vote of thanks to the President for his address.

Mr. Richardson seconded and Mr. Rippin (West Ham) supported.

The motion was carried by acclamation.

THE PARTHENON.

THE following translation of a letter from Dr. Dörfeld appeared in the *Times* on Thursday:—

"The Parthenon is doomed!" Thus begins an article in your issue of August 14, which has created a sensation not only in England but throughout Europe. Is the Parthenon really doomed? Is this gem amongst the monuments of the world irreparably lost? Is it impossible to save it?

As a student well acquainted with the Parthenon, and as a member of the committee appointed by the Greek Government to superintend the repairing of it, I think I may assert that the temple is by no means yet doomed. The condition of the structure is certainly not satisfactory. Earthquakes and fire, rain and sun, frost and heat, several bombardments, and more especially the unfortunate explosion of the Turkish powder magazine by the Venetians under Morosini in 1687, have all contributed to annihilate entirely large portions of the temple and severely to injure those still preserved, and even to destroy in many places the beautiful white marble. One has only to read the reports of the three distinguished European architects—the Englishman, C. F. Penrose, the German, T. Durm, and the Frenchman, T. Magne—on the state of the temple, in order to satisfy himself that the structure has indeed suffered severely, and that the condition of certain portions is even dangerous. But, according to the undeniably authoritative opinion of those architects, the damage is not so serious as your correspondent describes it; and, on the contrary, the preservation of the existing structure for hundreds, and perhaps thousands, of years is still possible. One thing only is necessary, viz. that the proposed repairs shall be carefully and expeditiously carried out. The same conclusion has been arrived at by the committee of Greek and foreign architects and archaeologists to whom the Greek Government has entrusted the task of superintending them. As the opinion of all these experts with regard to the mode of restoration shows few divergences, the work might be taken in hand at once, those repairs being undertaken first upon which all the experts are agreed.

Last winter a solid scaffolding was erected along the western portion of the temple in order first of all to replace the specially damaged epistylum beams of the opisthodomus by new ones. The stones required for this purpose had in part been already brought from Pentelicon to the Acropolis and the machinery obtained for raising these huge blocks, and work was about to begin when war unhappily broke out and arrested the progress of operations. The funds for the work of restora-

tion were granted by the Greek Archæological Society, which derives its large revenues from a lottery sanctioned by the State. This year, unhappily, owing to the disastrous war, the lottery has hardly produced anything, and the society has consequently no funds at its disposal to prosecute the works. The repairs have therefore been temporarily interrupted, and who knows when they may be resumed? For the Parthenon this is a deplorable matter, and the consequences may be most serious should a severe earthquake shake the mountain rock on which it stands.

Your correspondent then proceeds to point out how excellently, since the erection of the scaffolding, the remaining portions of the celebrated frieze, the wonderful masterpiece of Phidias, can be seen and admired, and suggests in this connection whether it would not be better to place the frieze itself in a museum, and to replace it on the temple by a copy. That suggestion I heartily endorse. Not only are the marvellous works of a Phidias exposed on the temple to a gradual process of disintegration under the influence of weather, but in their present position they cannot be properly seen and appreciated. Now for the first time, from the scaffolding which enables one to approach and study them at leisure, their great artistic merit stands fully revealed. If a modern sculptor or architect could set them up about 12 metres from the ground, in a gallery a little more than three (*sic*) metres broad, he might well afford to disregard scoffers and critics. And must we allow valuable Greek originals, numbered amongst the finest sculptures of the world, to perish slowly in a place where they might very well be replaced by copies? Your correspondent's assumption that the Greek committee has rejected the suggestion lest it should seem to justify *ex post facto* Lord Elgin's spoliation of the Parthenon is erroneous, for it was the English member of the committee who combated the proposal. Moreover Lord Elgin's action has been denounced not so much because he conveyed some of the sculptures into safe keeping in London, as on account of the barbarous manner in which he destroyed some parts of the temple—*e.g.* the mouldings of the south side—in order to remove the sculptures.

In conclusion, your correspondent rightly praises the Greek Archæological Society for the "wonderful progress" made in Greece with regard to the care bestowed upon the antiquities of the country. Certainly those who, having seen the Acropolis and the other ruins, and especially the museums, twenty years ago, revisit them now must be amazed at the progress to be witnessed on all sides. In Athens the ruins are protected from injury by iron railings, and the museums, which used to be described as stables, can stand comparison now with those of London and other European cities. This progress is undoubtedly due in part to the Archæological Society, but chiefly and in the first place to Mr. P. Kavvadias, the Director-General of Antiquities, especially since he has combined the secretaryship of the Archæological Society with the direction of the Antiquities Department of the Ministry. His energy deserves recognition, and your correspondent should not have omitted to mention his name.

FEVER HOSPITAL CONSTRUCTION.

A PAPER was read on "Fever Hospital Construction" by Mr. Edwin T. Hall at the Sanitary Congress in Leeds, on the 16th inst. The author said that the organised attack on such enemies as smallpox, scarlet fever, diphtheria, &c., was the outcome of the latter half of the Victorian era. Even in the county of London no hospital specially set apart for scarlet fever existed until 1849, when the London Fever Hospital was opened; and in the country generally local authorities first derived their power to provide hospitals for infectious diseases under the Sanitary Act of 1866. After enumerating the various powers granted for the erection of hospitals, he said that when public infectious hospitals were first erected in England it was common to devote a part of the site to smallpox and another part to all other infectious diseases, one set of staff quarters being common to both. It was, however, found that the danger from smallpox was great, not only to the sick patients in other parts of the hospital, but to the surrounding district, and separate hospitals were instituted for smallpox. In London the Metropolitan Asylums Board in 1885 came to the momentous conclusion to abandon land hospitals for smallpox and to establish floating hospitals on the Thames at Darent. The happy result followed that the disease had been practically exterminated in the Metropolis. The means by which this result was obtained demanded careful consideration. The value of isolation was shown in a remarkable degree and it was demonstrated that the fast travelling tide of the river caused by friction movement in the air even in the calmest days sufficient to carry away and oxygenise heavy gases. The perfection of the Board's ambulance service had greatly contributed to the result, and in any scheme of hospital construction for a town of any size too much stress could not be laid on the necessity for an ambulance station and an organised ambulance service. On the question

of the maximum size of an infectious hospital he had not been able to find any data to prove that any limit need be set. Given an adequate area of land and an adequate staff, a hospital might be of any size. The site for any hospital should be as open as possible. If one could be found surrounded by roads, it would be better, because all roads were channels for wind currents. It should be on elevated ground, so that drainage might be readily carried away, and should be as compact as possible. Much had been said as to the maximum number of patients per acre that should be put on the site, but he was not aware of any data that justified any one of the arbitrary figures suggested. The area required should be determined first in regard to the facilities which naturally existed for a rapid change of the surrounding atmosphere, and next the necessity for a zone between the infected buildings and the boundaries. The one-storeyed hospital was the medical ideal, but the practical suggested and permitted of the two-storeyed pavilion. There should be two entrances only to a hospital—one for the staff, patients and stores, and the other for the hearse, coffins, &c., the latter being so placed that it was out of sight of the patients. Having described the internal arrangements of several large hospitals, Mr. Hall then said the factor first to be considered in planning was how many patients should be put in a pavilion. In cases of scarlet fever, it was considered by medical men most economical from the nursing point of view to have not less than fourteen in a ward. The Asylums Board had fixed the number at twenty, and they might well accept that as a good rule for a large hospital. The best height for a ward from a practical point of view was 13 feet. Any greater height was not aerially of any value to the patient, and any less height in a large ward looked oppressive. It was of great importance to insure a uniform temperature to all parts of a pavilion, and he believed the best form of heating was by low-pressure hot-water radiators beneath windows. He deprecated horizontal pipes around the walls of a ward, and those in trenches were not to be tolerated at all. It was far better to put all horizontal pipes in the open basement beneath the pavilion. There should, in addition, be central fireplaces, which gave cheerfulness to the room, and were most valuable extractors of foul gases. In his judgment, a central stack was much better for an infectious ward than a stove with horizontal flues carried to the external walls. He believed in the artistic treatment of a ward as a refining as well as a curative value to patients, and thought that the surface of the walls of a ward should be of impervious material, faced with Parian, Keene's or Robinson's cement, painted in various artistic colours to rest and please the eye. In addition to the ordinary pavilion of a hospital, there should be what were technically termed isolation pavilions for the reception of cases of which the diagnosis was not certain. After dealing exhaustively with the fittings of a hospital, he said he would recommend as the motto for the inside of an infectious hospital, "Let nothing be hidden." In conclusion, he urged on all local authorities the desirability of making their hospitals architectural in treatment.

In the course of the discussion which followed the question of cost was raised. Mr. Hall, in reply, said that the cost of the Park Hospital would be under 400*l.* per bed. That, however, did not include the cost of the land, which was 13,000*l.* The cost of St. Thomas's Hospital, which was not an infectious hospital, was 500*l.* per bed.

GLASGOW ARCHITECTURAL ASSOCIATION.

ON Tuesday evening, the 14th inst.—the vice-president, Mr. George S. Hill, in the chair—the honorary president, Mr. James A. Morris, delivered a lecture on "Attainable Ideals." The lecturer exhibited on the walls a unique collection of working drawings, which he had specially obtained from some of the principal English architects, including the late John D. Sedding, John Belcher, Ernest George & Peto, Ernest Newton, C. F. A. Voysey, R. Schultz, Balfour & Turner, and Dunn & Watson. With these as his text, the lecturer showed how lofty ideals and noble sentiments were bound to raise and ennoble the work of an architect, notwithstanding the apparently insuperable checks which beset him. He referred reverently to the late John Sedding, who though dead yet spoke powerfully to us. "His drawings show abundantly his vivid imagination, his keen desire for perfection and the infinite labour he gave in seeking it, his nervous directness of touch, his refinement, breadth, simplicity and power." He spoke of Norman Shaw as, of those living, the first to build again on English soil on English lines, and asked that Scots architects might turn more towards the simple dignity of their own country's ancient work. He called attention to the care bestowed on the gardens, and said that the simple beauty of a fountain, a sundial or a dovecot often appealed to one more than buildings of massive grandeur. Mr. Alexander M'Gibbon proposed a vote of thanks to the lecturer. The Chairman expressed the sincere obligation of the Association to those architects who had so kindly lent their drawings. He then seconded the vote of thanks, which was heartily accorded.

NOTES AND COMMENTS.

THE people of the United States appear to be becoming more and more restrictive, as is usually the case when an economical error finds approval. The time seems to be fast approaching when every State will regard neighbouring States as foreign countries. A case indicative of the tendency of the time has occurred at St. Paul, Minnesota. A new capitol is to be erected, and the Commissioners, acting on the advice of their architect, obtained stone from quarries outside the State, because it was considered to be more enduring than any stone to be found in Minnesota. The outcry that followed could hardly be more violent if an act of high treason was committed. However, it is satisfactory to find that one newspaper is courageous enough to resist the phrensy which selfishness inspires. The *Pioneer Press* says:—"If this abuse was dictated wholly by considerations of State interest and State pride, it would not shut wholly out of view that the highest and noblest consideration of State interest and State pride is that which concerns the character of the building itself. To the people of the State at large, and to their children and children's children, it is of infinitely more importance that the architecture of the building should be worthy of the State and represent the best artistic beauty and nobility attainable with the means provided, than that it should be simply an advertisement in stone of somebody's private interests in a local quarry. It is a fortunate thing for the State that the selection was in the hands of a Commission, superior to the narrow provincialism which would sacrifice the beauty of the structure to the clamour of local interests." It is possible to neglect local interests overmuch, but the conditions under which elected authorities exist do not allow an error of that kind to be often repeated.

THE Musée Carnavalet is not, we believe, included in Messrs. Cook's programme of the sights of Paris which are worth visiting, but we suppose no English antiquary has visited the old house without wishing that London could possess a similar exhibition. The rooms recall Madame Sévigné and the fine ladies whose wit, beauty and learning gave charm to the court of LOUIS XIV. But the contents were mainly reminiscent of the Paris of that era, and more especially of the Revolution. Vivid as are the scenes in CARLYLE'S "French Revolution," they become still more impressive after a few visits to the Musée. If numerical tests are applied the Musée Carnavalet is not as popular as the Musée Guérin, although one is free and the other costs at least a franc. Its situation is not adapted to allure strangers or citizens, and French people sometimes say they have had more than enough of the blue stockings of the age of LOUIS XIV. and of the frail but patriotic THÉROIGNE DE MÉRICOURT, the MAILLARD who served as Goddess of Reason and other questionable demoiselles with whom began the Women's Era in which we have to live. The Musée is, however, undergoing a transformation, and it is not unlikely to become one of the most popular resorts. M. GEORGES CAIN, who has painted so many pictures to the honour of the Vendéans and the Royalists who were opposed to the Revolution, some months ago accepted the curatorship, and having wisely devoted himself at first to the study of the works which are under his care, is now taking measures to display them to the utmost advantage. His aim will be to demonstrate the grace which was to be found in Paris not only in the grand days of LOUIS XIV., but even amidst the terrible scenes of the Revolution. There are more works of interest in the Musée Carnavalet than can be seen. It is, therefore, decided to give all of them a turn, and consequently the aspect of the rooms will vary from time to time, and the constant visitor may expect to have his assiduity rewarded by the sight of novelties.

M. CHARLES GARNIER is not to be envied at the present time. He is naturally anxious for the stability of his opera house, which is a guarantee of his fame, but it would be only mock modesty on his part if he did not feel convinced that the building is an adornment of Paris which would be very much poorer if by any accident the safety of the structure were endangered. But the architect is not master and dare not do what he likes with his creation. It is part of the national property, and therefore an army of officials

have power over it in various ways. Men of that class are alike all the world over, and it is no doubt a pleasure to them whenever they are able to ignore the architect. One opportunity which they realised is just now causing much anxiety to M. GARNIER. The building is lighted by the aid of electricity, as every opera-goer is aware. But it is not generally known that the generation of the electricity is accomplished in the basement of the building. The machinery was introduced and the process arranged in spite of M. GARNIER'S opposition. That was hardly prudent on the part of officials who are supposed to be men of science. It is true the basement of the opera house is of massive construction, with piers and vaults in which stone was not used sparingly. But however large a margin was allowed for contingencies it was not calculated that the piers were to be subjected to the effect of constant vibrations of a novel kind, for neither in Paris nor in London have adequate demonstrations proved what is the actual effect on masonry of such generators as are to be found beneath M. GARNIER'S building. There are other risks which have followed the introduction of electric lighting. M. GARNIER is now engaged in preparing a report to the Minister of Fine Arts on the subject. Of course it will be referred to engineers; but after the downfall of bridges and the collapse of reservoirs, which now are, apparently, only commonplace incidents, official engineers will do well to be less confident about their formulas, especially when they have to be applied to a building so varied in character as is the Paris Opera House.

DEPARTURES from by-laws appear to be punished rather severely in Paisley, and, as elsewhere in Scotland, defendants in such cases are tried by the Dean of Guild, who is the building authority. On Friday Mr. GOLD, a builder, was charged with a series of breaches of the regulations. The alleged offences were deviating from the plans passed by the Dean of Guild Court, leaving the paving of a court incomplete, deficiency in drain-pipes, unfinished closets, leaving a gable exposed to damp, constructing a ceiling of the height of 9 feet 4 inches instead of 9 feet 6 inches, allowing houses to be occupied before a certificate was granted by Master of Works. Fines amounting to 30s. were imposed. Defendant's counsel gave notice of appeal.

THE new illustrated book, "The Chippendale Period in English Furniture," by Mr. K. WARREN CLOUSTON (DEBENHAM & FREEBODY and E. ARNOLD), must not be taken as a reproduction of Chippendale designs. It is a treatise on the furniture and decoration of the eighteenth century. CHIPPENDALE and his contemporaries appear as a part of a group which in addition consisted of Sir WILLIAM CHAMBERS, the brothers ADAM, SHEARER, HEPPLEWHITE and THOMAS SHERATON. CHAMBERS'S influence is explained as it deserves, for, although the wits of the time made merry over his Chinese exercises, shrewder men translated them into forms which seemed less strange and gained reputation for originality. Mr. CLOUSTON is apparently an enthusiast for the style. At all events he has an expert's knowledge and describes an immense number of examples in such a manner as will compel admiration from those who may not believe in the superiority of CHIPPENDALE and his imitators. The illustrations are charming. Some appear to be reproductions of fine engravings, others of original drawings; but there is such general uniformity of treatment and lightness of touch it becomes impossible to say which was drawn by an eighteenth-century Frenchman and which by Mr. CLOUSTON. The book is certain to receive much admiration from amateurs, which it undoubtedly deserves.

HOUSE OF THE PLANTIN FAMILY, ANTWERP.

EVERY visitor to Antwerp who cares to form a mental picture of the sixteenth century should not fail to visit the house and printing office which belonged to CHRISTOPHE PLANTIN. The property was purchased by the municipality at a cost of about 50,000*l*. It is preserved in a manner which does credit to the authorities, for they endeavour to uphold the memory of the man who was the foremost printer and publisher of his time. His name is not only associated with the property which is known as

the Musée Plantin, but it is also attached to one] of the finest streets in the city.

PLANTIN deserved the respect he has obtained. By birth a Frenchman, he managed to secure the patronage of the Emperor CHARLES V. and of his son and successor. This gave him the privilege of printing the service books and Bibles for churches in the empire and colonies. It was practically a monopoly of the ecclesiastical printing for all Christendom. PLANTIN could not have obtained so much if he did not possess learning as well as character. He was recognised as one of the most versatile scholars of the age,

THE HOUSE OF THE PLANTIN FAMILY, ANTWERP.

and was competent to test the accuracy of any book printed by him, whatever the language. Throughout his life his enthusiasm for books exceeded his financial interest in them.

It was about 1550, when the Renaissance had gained a firm footing in Flanders, that CHRISTOPHE PLANTIN set up his printing-presses in the street which is now known as the Rue Haute Rivage. The surroundings of the place in those days are not to be judged by their existing state. A more eligible site for such a business as PLANTIN's could hardly be found in Antwerp. It was near the river and the despatch of his folios to foreign parts was facilitated. If an imprimatur were needed the cathedral was close at hand. The Dominicans who would occasionally have to be consulted were not far off. From his influence with the Court PLANTIN could select any site he pleased, for there were reasons which made his residence in Antwerp a necessity. It was an advantage to the Government to enable the subjects of the empire to be independent of foreign printing, and moreover there was an opportunity afforded to interfere with a new variety of English trading, for Antwerp had become the printing and publishing office for the translations of the Scriptures by the Reformers. WILLIAM TYNDALE for a time resided in Antwerp to direct the publication of his Testament.

It was probably owing to imperial subsidies that PLANTIN's works were erected in a style that amazed the sixteenth century. GUICCIARDINI described them as among the wonders of Europe, and apparently they surpassed all the secular buildings which were then to be seen in Antwerp. PLANTIN's printing office, says ISAAC D'ISRAELI, was "magnificent in its structure; it presented to the spectator a countless number of presses, characters of all figures and all sizes, matrices to cast letters, and all other printing materials, which BAILLET assures us amounted to immense sums." If compared with some of the modern printing offices of Belgium PLANTIN's establishment would not look like a marvel, but in all such cases the standard of the time should be applied.

PLANTIN's love for his work is suggested by the union of his residence and works, which have been erected around a courtyard. He wished to be always able to have conversation with the scholars he engaged to read his proof-sheets, with his compositors, type-founders, engravers and binders. They all appear to have formed one family, and it may be one as happy as could be found in Antwerp. PLANTIN was also, we imagine, an experimenter. There is a small room in the house which was apparently used as a laboratory for type-founding on a small scale, and it may have been closed to all but the master. The conditions of his employment, however, prevented the introduction of novelties such as the italics of ALDUS. And in his ornamentation he had to be sparing. A suspicion of innovation would have injured his reputation among the clergy; accuracy and legibility were his principal aims. CHRISTOPHE PLANTIN lived until 1589, but his printing offices in Paris and elsewhere were afterwards conducted by his sons-in-law.

On visiting the premises we can easily imagine that we have arrived at a moment when the PLANTINS and their employees happen to be away, but are soon expected. This arises from the care taken to avoid the appearance of an ordinary museum. The rooms contain no more furniture than would be seen in them in the sixteenth or seventeenth century. In the large dining-room, which was, we suppose, generally used as a place of meeting for principals, artists, engravers, &c., examples of books produced by the PLANTINS are to be seen, as well as proofs of plates, title pages and ordinary pages bearing corrections. TURNER was not more careful with the mezzotints of the "Liber Studiorum" than was RUBENS with plates copied from his drawings for missals. He was most elaborate in his written instructions, and suggested effects with his usual vigour of hand. In the printing office there was apparently no lack of liberty. The readers sat together, and could, when necessary, discuss difficulties without fear of interrupting labour. We can see the proofs tied up in small parcels as if awaiting for a resumption of the hours of labour, and the quill pens are ready to be used. Compositors and pressmen also worked under favourable conditions, an abundance of light being one of them. In the arrangement of the

place everything is done to suggest that all things are left as they were in the days of the PLANTINS, and from courtyard to attics there is not a trace of theatricalism.

MUNICIPAL ENGINEERING.

A LECTURE on the "Sanitary Advances in Municipal Engineering" was delivered in Leeds by Mr. H. Percy Boulnois, city engineer of Liverpool. He began by calling attention to the multitude of subjects which a city engineer was expected to know something about. These included amongst many others, sewerage, bridges, water, road-making, tramways, street lighting, architecture, surveying and building. Marvellous progress had been made in municipal engineering during Her Majesty's reign. The municipal engineer, or town surveyor was practically unknown before the Queen came to the throne. He took great credit to himself and his brother officials for the work which had been accomplished in the face of great opposition during this comparatively short period. Municipal government theoretically was splendid; practically, it often failed. It failed principally because that government was ever changing. As each succeeding November came round fresh men took seats on the controlling bodies. The consequence was that the municipal engineer had no sooner educated one committee to a proper standard than he had to start to educate another. This was very much against advancement. Then, again, in small towns men got into municipal bodies very often for purposes of their own. It had been found that a ready "spouter" was more likely to be elected than a man who had the interests of the place at heart, but who could not speak very well. They were all agreed upon the marvellous strides that house drainage had made during the last few years. This was in no small measure due to the wonderful work accomplished by their chairman, Mr. Pridgin Teale. His book particularly drew attention to the defects of sanitation in this direction. It aroused interest in the subject, and that was more important even than legislation. Education was first, legislation afterwards. Sewerage used to be exceedingly defective. The drains were badly constructed—mere elongated cesspools. But the municipal engineer had changed all that. He had taken up the matter scientifically. He had properly graded the drains, and consequently large communities were now able to live together with almost perfect immunity from disease. He drew attention to the difficulties experienced in insuring that sewers shall be self-cleansing, and described the various methods of flushing which have been adopted. By means of automatic flushing tanks placed at the head of the sewers, or by large tanks which might be placed over the sewer manholes, the whole of the contents could be passed into the sewer. A tank of this description, which could pass 2,000 gallons of water to the sewer in 30 seconds, was described. Liverpool flushed all its sewers, including those of private houses, large and small, twice a year, at a cost to the local authority of over 4,000*l.* per annum for private flushing alone. If a householder wished to have his dwelling flushed out of its turn it was done at a nominal charge, according to the rateable value of the premises. Thus not only were the drains of a house flushed, but if defects in the main drains existed they were reported and remedied. Great progress had been made in sewage disposal. Much, he thought, might be said for the septic system, under which decomposition was allowed to proceed in tanks, under safe conditions, the effluent being passed through filters. In this way nature was followed, and not arrested, as it usually was by most processes of chemical treatment. Under the septic system, decomposition, that great law of nature, was allowed to step in and, by breaking up the constituent parts of the sewage, rendered the effluent the more amenable to nitrification. He wished Mr. Cameron all the success he deserved with reference to the discoveries he had made on this point, and that wish was emphasised by the fact that that gentleman was at one time his assistant. With the important work of scavenging the lecturer dealt at some length, recommending refuse destruction by burning over every other method of dealing with the enormous accumulations of house and trade refuse which had daily to be collected in every large city throughout the country. Want of time, remarked Mr. Boulnois, prevented him from alluding to sanitary advances in connection with water supply, ventilation, heating, &c., but he dwelt upon the question of sanitary road-making, and pointed out that a properly paved roadway upon a good bed of Portland cement concrete was impervious and absolutely sanitary, whereas a macadamised road for busy traffic was unsuitable on account of its porous nature. A street properly paved with Australian hard wood approached as nearly as possible perfection in street making from all points of view. Turning to the debateable question of the housing of the labouring classes, the lecturer urged that the persons for whom the benefits of the various Acts of Parliament were intended are the "labouring" classes and not the "artisan"

classes, who had better wages and could afford to live in houses provided by private enterprise. With regard to the labouring classes, whose wages were precarious and sometimes very small, it was essential that they should be housed in cheap homes at a rent of about 1s. per room per week, and that these houses, though sanitary in every respect, should not be made too attractive, or they would induce the artisan classes who could afford a dearer class of house to occupy them. Such houses could not be built on the ideal as to how these people ought to live. It was this higher ideal which had practically prevented the benefits which should have been derived from the various 'Labouring Classes' Dwellings Acts being enjoyed by the classes for whom they were passed. He stated that in Liverpool cheap houses were now being erected by the Corporation, which were letting as fast as they could be erected at 1s. 3d. per room per week, and that the net return for these houses would be nearly 5 per cent. per annum on the outlay. The lecture was illustrated by a variety of lantern slides, and throughout it was listened to with marked and close attention, the various points raised being followed with much interest.

Mr. Pridgin Teale, chairman, remarked that Leeds citizens must have been deeply interested in the way in which the lecturer had met the difficulty with regard to the housing of the working classes by a compromise between the self-contained cottage, to which they had been accustomed, and the palatial tenement houses, which were all the less popular for being larger, and which could not be erected at a cost that the people for whom they were intended could pay. Being fond of wood pavement he was glad to hear of a sort of wood that was what Leeds wanted.

THE BRITISH MUSEUM.

THERE are not many Blue Books which are as satisfactory reading as the annual returns of the British Museum, and this year the document is of more than average interest. The Trustees endeavour to adapt the great institution under their control to the wants of the times, and now it can be said with truth that there are no museum galleries in Europe which contain more objects that are deserving of study or which afford more opportunities to students. The appreciation of the collections is suggested when it is found that the number of visitors to the Museum (in Bloomsbury) was 581,906 during last year, the highest number reached since 1890. In the reading-room there was a further decrease, but that is accounted for by the growth of local libraries in the Metropolis. But if readers declined there was an increase in the volumes consulted, the number for 1895 being 1,405,866, while last year it was 1,428,535.

The acquisitions for the various departments have been important. For the library the most remarkable is Macho's French Bible, or rather abridgment of the Scriptures, printed at Lyons for Bartholomew Buyer about 1477, one of the rarest and most important of old French books, the first containing woodcuts, the first in which the place of imprint is specified and preceding the first actual translation of the Bible into French by more than forty years. Only five other copies are known, and only one of these is perfect. The slight imperfection of the present copy is owing to two duplicate leaves having been bound up by mistake and the right leaves omitted. The late Sir A. W. Franks presented a strange proclamation of Henry VIII. for diminishing extravagance in living:—"Prouysion made by the King's hyghnes and his counsaill for puttynge a parte the excessyue fare and redusyng the same to such moderacion as folowyngly ensueth." Imprinted by Richarde Pynson.

Miss Frapp has given Barrett's "History of Bristol," bound in nine volumes, and interleaved with water-colour and pencil drawings, chiefly executed by herself; engravings, lithographs and other illustrations of Bristol, and accompanied by a collection of Bristol municipal seals.

Among the older manuscripts acquired during the year one of the most important is the so-called gospels of St. Grimbald, a fine copy of the four gospels in Latin, written and illustrated early in the eleventh century in the monastery of Newminster (afterwards Hyde Abbey) at Winchester. It is decorated with miniatures of the evangelists and elaborate borders in gold, silver and colours in the best style of English art of the time. At the end is a copy of a letter from Fulk, Archbishop of Reims, to Alfred the Great, recommending Grimbald, a monk of St. Bertin, who was invited by Alfred to England and became first abbot of Newminster. The following additions to the manuscripts are also interesting:—

Six volumes of notes and drawings made or collected by the late Professor John Henry Middleton, chiefly for his work, "The Remains of Ancient Rome," 1885.

Four volumes of rubbings of brasses selected from the collections of Sir A. Wollaston Franks in order to supply the deficiencies of the several series already in the Department.

Descriptions of brasses in English churches, by the Rev. Henry Addington, nineteenth century.

Eight volumes of collections made by Thomas Willement, with coloured drawings, &c., relating to the history of stained-glass, nineteenth century.

The drawings have been enriched by the purchase of one of the finest known works by Michel Angelo, representing the Lamentation of the Virgin and the Disciples over the body of Christ. It is in black chalk, and on the verso is a sketch in red chalk, apparently for one of the captives designed for the tomb of Julius II. This drawing is from the collection of the Earl of Warwick.

The original design for the engraving of Venus in a landscape, by Domenico Campagnola, has been presented.

Two portraits of San Carlo Borromeo, one taken after death, in black and red chalk, by Ambrogio Figino; and a sheet of studies in red chalk, drawn on both sides, by Andrea del Sarto, have been taken from Lord Leighton's collection. Among the studies are two for the head and figure of St. John in the picture of the Virgin and Child with St. John at Hertford House, and a study for the figures of St. Bruno and St. Onuphrius in the picture of the Madonna with Saints, now at Berlin. The following English drawings have been secured:—

An album of thirty-four pencil sketches, chiefly groups of French peasantry, by Richard Parkes Bonington.

Eighteen sketches of figures, by John Constable, R.A.

A drawing in sepia and Indian ink of a cart passing along a country road, by Thomas Gainsborough, R.A.

Sixteen original designs for the series of prints entitled "Industry and Idleness," by William Hogarth, eleven of them being finished drawings for the engraver, and the remaining five first sketches, including two for subjects not used in the engraved series.

Two portraits of ladies, black and red crayons, by John Hoppner, R.A.

Figure of a cavalier, a pen and ink sketch, and two sheets of pen and ink sketches of stags and hinds, by Sir Edwin Landseer, R.A.

Portrait of a gentleman, a life-sized head, black and red chalk, attributed to Sir Joshua Reynolds, P.R.A.

A sketch book of forty-three leaves containing pen and ink drawings, by George Romney.

A portrait of Samuel Palmer, the water-colour painter, by Henry Walter.

View of Roslin Castle and the companion in water colours, by Hugh William Williams.

The additions to the Egyptian and Assyrian antiquities usually appal from their quantity. The soil might be supposed to produce antiquities as soon as one crop is removed. Such an item as "A collection of 4,762 Babylonian contract and other tablets belonging to the period which lies between B.C. 3000 and 2000," and "A group of circular clay tablets inscribed in Accadian with public accounts, lists of revenue and produce, drawn up for the city of Ur, about B.C. 2300," must give rise to doubts whether it is possible for any individual to be acquainted with the contents of the Department. Another wholesale acquisition is "A collection of blue and green glazed *faience* figures of gods, priests, animals, &c., of the period which lies between B.C. 1000 and 600." The archaeologists, if there are any, who can appreciate collections as if they were to them no more than individual objects are to be envied. To the majority of people who have an interest in antiquity an addition like the following seems more easily grasped, and is therefore more interesting:—"Four painted *cartonnage* cases made to resemble the forms and faces of the dead bodies over which they were placed. They are all made of waste pieces of papyrus, and judging from the style of the Greek writing which is found upon them, cannot be older than the second century of our era. Names of the people for whom they were made appear in demotic, and mythological and other scenes are painted upon them in a manner which suggests that their true significance was not known to those who copied them on to the cases." It is curious to find with the Egyptians some decorators who were little better than machines, yet the absence of interest in their work after so many years becomes a quality which is more prized than spirited execution.

In the Department of Greek and Roman antiquities many valuable additions are to be found. Foremost comes from Clazomenae in Ionia a sarcophagus with gabled cover, painted with representations of battles, an inroad of Cimmerians into Asia Minor, funeral games, animals and decorative patterns; Ionian art of sixth century B.C. There is no finer example of terra-cotta in the Museum. The battle scenes now appear to be little more than monochromes, but the animation seen in them is marvellous. There are other figure scenes which are symmetrically arranged, and architectural ornament. The production of so large an example of terra-cotta without any wind ing or irregularity in the lines indicates the skill attained by the Ionian potters. The sarcophagus is placed in a position where it can be studied on all sides and within as well as without.

The following are some of the acquisitions illustrative of Mediæval art:—

Circular gold medallion with a bust of Our Lord in cloisonné enamel; Byzantine work of the tenth century. Portable altar of porphyry mounted in copper gilt, and engraved, having at the corners the emblems of the Evangelists in champlevé enamel, from Avignon; French work of the thirteenth century. A holy water bucket of gilt copper, with translucent enamel medallions, probably Spanish, of the fourteenth century, obtained in Saragossa. A reliquary of rock crystal and silver gilt in the form of a church; French, fourteenth century. A pair of altar candlesticks of copper gilt, and engraved in open work with monsters and with large crystal balls, from a church at Adana, near Iskanderun; French work of the thirteenth century. Reliquary in the form of a figure of the Virgin seated, with shield of arms in champlevé enamel, copper gilt and engraved with figures of Our Lord and two disciples; French, thirteenth century, from the East. Small seal of green stone with a figure of the Virgin; Byzantine, tenth century. Copper badges enamelled with armorial and other devices; from Spain, fifteenth and sixteenth-century work. Pair of candlesticks of bronze engraved with minute ornament, outlined with silver; Venetian, early sixteenth century; and three German brass salvers of the fifteenth century, one of them of unusual size. A hook of iron, inlaid with bronze of Arab work, and two other pieces of similar work inlaid with silver. Bronze celestial globe, made from the design of Abu'l Husein Abdelrahim es Sufy in the year of the Hejira 834 (= A.D. 1430). Another made by P. Petit, 1659. A cup dial of copper gilt, made by Bartholomew, Abbot of Aldersbach, in Bavaria, 1554. A cube dial by D. Beringer, seventeenth century. A copper gilt folding dial by Hans Troschel, 1609, another of ivory by the same maker, and a third, of ivory, by Conrad Karner. A brass square with radial index, German, dated 1573; a gunner's level engraved with Mars, and another by G. Z., 1619. Square dial made by J. Ramminger, of Stuttgart, 1704. Bronze model of a church with square tower; Italian, early fifteenth century. A brass case with an elaborate inscription and designs; it appears to have belonged to some object made for Marc Antonio Fregoso, son of a doge of Genoa, in 1516. A statuette of the Virgin and Child; Flemish, late sixteenth century. A carved horn box, medallion portrait of Victor Amadeus III., of Sardinia.

Terra-cotta figure of Neptune, a design for a fountain, probably Florentine work of the sixteenth century, presented by Baron Ferdinand Rothschild.

A pear-wood mould for making relief portraits of George Duke of Saxony, 1530-39, a work of unusual excellence; a cuirbouilli powder-flask, with a fleur-de-lis, sixteenth century; a casket of the same material of the seventeenth century and an engraved gourd.

Although numerically not in excess of the average the most valuable additions of any one year of the present century have been made to the Department of Coins and Medals. Altogether the additions amount to 1,492, of which 296 are gold and 881 silver. Among the British coins a few are described; one is a gold stater of Eppillus, a chief who ruled in Kent, son of Commius and brother of Tincommius and Verica. The only other specimen of this coin is in the collection of Sir John Evans. Another is a gold stater of Epaticcus, son of Tasciovanus and brother of Cunobelinus (Cymbeline), king of the central districts of Britain. Various other rare coins of Tasciovanus, Cunobelinus and of the Iceni have been acquired. One of the pennies bears the name of Jaenberht, Archbishop of Canterbury, A.D. 766-90, on the obverse, and that of Offa on the reverse. It was during Jaenberht's episcopate that Kent was conquered by Offa, and it was by his authority that this archbishop was allowed to issue coins. There are also pennies issued between A.D. 793 and 914 by Archbishops Aethelheard, Wulfurd and Plegmund. Another Canterbury coin is of the reign of Eadweard II., A.D. 975-79. Numismatists may set more value on an unique coin of the highest historical importance, as it was struck in London in A.D. 872, when Halfdan held the City for a short time before his assumption of regal power in Northumbria. The monogram of the name of London on the reverse was afterwards copied on the coins of Alfred the Great.

Other British coins of more interest are a unique penny struck at Darenth, Kent, and another struck at York, having a view of the tower of the Minster, in the reign of Æthelstan, A.D. 925-40. A large series of coins of Cnut, Harold I., Harthacnut, Eadweard the Confessor and Harold II., and a penny of the last which was struck at Chelsea, being the only evidence of the existence of the mint, are also added. A half-crown and a shilling of the reign of Elizabeth show that "milling" was understood, if not practised, in that reign. The golden five-broad piece, known as the Juxon medal, has at last found a worthy asylum in the Museum.

Some of the Greek coins are remarkable for their beauty, others for their historic interest. A nummus of the town of Terina (B.C. 440-400) bears on the reverse an exquisite winged figure holding a wreath and a caduceus, and seated on an overturned amphora. One of the seven varieties of the Lysimachian gold stater is of rare beauty. A head of Apollo on a tetradrachm

of Chalcidice is of the highest art. On a stater from Cyrene (B.C. 431-321) is a quadriga driven by Nike and seen from the front. A splendid gold Syrian stater is of great value, both historical and numismatic, for it represents the statue of Zeus in the temple of Antioch, holding the golden Victory which Alexander Zebina (B.C. 128-123), when hard pressed for funds, melted down to coin into money for the payment of his army, "Jovis solidum ex auro signum Victoriae tolli jubet." A tetradrachm of Lacedæmon is also precious, first, on account of the portrait, the only one extant, of the famous tyrant Nabis, B.C. 206-192, and next on account of the reverse inscription, from which we learn a fact mentioned by no historian, viz. that Nabis assumed the title of king.

There is much else among the acquisitions in the departments which will repay attention, and in fact the British Museum becomes more and more attractive as time runs on, and regular visits to it are necessary on the part of all who desire to become acquainted with the branches of art which are represented by the collections.

DISINFECTING PROCESSES.

IN the section of Sanitary Science at the Leeds Congress a discussion on the subject of "Disinfection" was opened by Dr. Spottiswoode Cameron, medical officer of health for Leeds, who said he would try to point out the way in which they treated infectious diseases in Leeds, and he would state a few of the difficulties he had personally encountered, in the hope that those who followed would help him out of them. Medical officers had, generally speaking, to deal administratively with the subject of disinfection, but there was a large and increasing army of men who were able to deal in the laboratory with the processes which he and others had to put practically into force. Medical officers looked to such men for guidance in the selection of the agents they employed. They might roughly divide infectious diseases, with regard to which they employed disinfectants, into two classes. There were diseases, like smallpox and typhus, where the infection went from person to person in an epidemic form, and there were diseases, such as typhoid and probably cholera, where the germs were more localised, and were contained more or less in the secretions or excretions of the body. In diseases like typhus and smallpox it had always seemed to them there that the most important thing to attack was the clothing of the patient, and the same was the case with scarlet fever. They might disinfect clothes in two ways. They could reform them altogether by burning them up, and that was the line adopted during an outbreak of smallpox in some of the smaller districts of Yorkshire. But that was not, strictly speaking, disinfection. Fortunately they had an agent which was capable of absolutely destroying bacterial organisms, and that agent was heat. The question was how to apply it, and here they had been tremendously helped by the investigations of Koch and by the masterly exposition of the subject by Franklin Parsons in the report of the Local Government Board. They had also had the assistance of a man like Washington Lyon, who had invented a machine which to a large extent carried out the conditions they sought; but there were one or two little difficulties in the application of heat by means of steam, which they were in danger sometimes of overlooking. If they put the garment saturated with the poison of fever or smallpox into a chamber in which steam, developed from water, at a pressure of 10 or 15 lbs., was allowed freely to escape, there was no doubt that in, say, fifteen minutes the bacteria would be destroyed. But if they took the water away, and had only the steam, and if then, in order to be doubly secure, they superheated the steam, they ran the danger of producing no result whatever. Their very anxiety to do the thing thoroughly might lead to their doing nothing at all. The points they had therefore to consider were, first, the selection of their apparatus, and secondly, the way in which it was worked. He was not saying anything against Mr. Washington Lyon's excellent machine, but was urging that care should be taken not to superheat the steam. He need not enlarge on the necessity of using separate vans and staffs for the conveyance of the clothing to the disinfector, and for its removal respectively. Then, how were they to deal with infected houses? In Leeds they emptied the house, stripped it of its paper, and dealt with the walls in various ways according to circumstances. In some cases, where the walls were painted, they washed them with a weak solution of corrosive sublimate, and afterwards washed it off. The object was to get the original coating of the walls away and leave a perfectly clean coating. Then in a great many cases they put a pan of burning sulphur in the middle of the room and closed the windows and doors. The latter proceeding was a debateable one. He was not prepared to say it did any good, but he was quite certain it did no harm. The question was, Why did they do it? From the time of Homer it had been the practice to burn sulphur where a place was infected, and if they had not done so, it would have been supposed they had not read their Homer properly, and that was an accusation they would not

like to have brought against them. But the practice had this advantage. The sulphur created such a horrible smell that it induced the people to open their windows and doors freely. It was all very well for the inspectors to open the doors and windows, but in the absence of such an inducement to keep them open as that he had described, many people would close the doors and windows as soon as the inspector's back was turned. In the matter of personal disinfection the difficulty was the choice of material. In Leeds they used about the weakest disinfecting agent, namely, carbolic acid. He admitted it was a weak one, but they used a good deal of it. They used it for one reason, because they could get the acid, in its impure form, of guaranteed strength in phenols at a very low price, and they could ascertain it did possess this strength. There were other and more powerful disinfectants in the market—and some of them were said not to be poisonous—but his difficulty was this: how were they to test them, and to know that the material sold to them was of the strength of the sample submitted for examination? He did not mean to say that a manufacturer would knowingly palm an inferior article upon them—far from it—but how was a manufacturer to know himself that he was now sending out the same material that he had put on the market six months or two years ago? They would agree that there was a risk with the adoption of improved chemical processes, of the later material being less powerful in its germ-destroying properties than the original samples. In this matter he hoped bacteriologists would come to the rescue of medical officers, and enable them to test by some standard method the germ-destroying strength of the disinfectants they were using.

Professor Delépine, who followed, describing experiments on tuberculosis organisms, said the bacteria resisted exposure to sulphurous acid for a very considerable length of time, and without showing any loss of vitality. Even chlorine produced very little more effect on them. The use of hyper-chlorate was then suggested. No doubt chlorine in itself was a very powerful disinfectant, but it required the presence of moisture by combination. He advised the use of hyper-chloride of lime for the purposes of experiments. As it was, however, no use obtaining it in its pure state, they employed simple bleaching powder, and it was found that when it was kept in contact with a certain amount of water for a few hours an active hyper-chlorate was generated. On a weak solution being applied to walls impregnated with the tuberculosis germs, thorough disinfection was obtained in a few hours. An exposure of a few minutes was generally sufficient. These experiments led him to try the action of hyper-chlorates on other germs, and in every case it was effectual, a weak solution destroying the vitality of anthrax spores in a very brief period.

Mr. Henry Kenwood, medical officer of health at Stoke Newington, read a paper on the "Disinfection of Rooms by Formic Aldehyde Vapours." He described a lamp which he had had made for the purpose of generating the vapour, and gave a number of conclusions as to the relative efficiency and advantages of different methods of charging rooms with the vapours.

THE ATMOSPHERE OF LEEDS.

A PAPER by Messrs. Henry Crowther and Richard Reynolds, entitled "A Decade of Sunshine Observations," was read at the Sanitary Congress. They said that ten years ago the Leeds Philosophical and Literary Society added daily records of sunshine to its meteorological observations. It was obvious that the area of the city would include localities varying in the amount of sunshine which they enjoyed, and the following three stations were selected for observations:—(1) The Society's museum, situate in the centre of the city, elevation above the sea 145 feet; (2) Woodhouse Cliff, one and a half miles north-west from the centre of the city, elevation 330 feet, residential suburb; (3) Lawnswood Cemetery, Adel, four miles north-west from the centre of the city, elevation 475 feet, on the fringe of the city. During the years from 1887 to 1896 the sunshine registered was—At the Museum 10,140 hours, at Woodhouse Cliff 12,250 hours, and at Adel 13,512 hours. The deficiency at the Museum from Adel was a mean percentage of 25·4 for the ten years, the deficiency at Woodhouse Cliff from Adel being 9·4 per cent. The recording station at Adel was selected under the belief that the sunshine there was but little obstructed by the smoke of the city, and that Adel consequently represented the type of the normal atmosphere of the locality. Woodhouse Cliff was about half-way between Adel and the Museum, and its records of sunshine were nearly always intermediate between those of the two other stations. When the observations had been continued for a year or two they were recast in order to distinguish any differences between the records of Sundays and working days. The mean for the ten years was as follows:—Museum—Sundays, 169 hours; other days, 140 hours. Woodhouse Cliff—Sundays, 193 hours; other days, 171 hours. Adel—Sundays, 203 hours; other days, 191 hours. It was thus seen that on days other

than Sundays the normal sunshine at Adel lost 26·7 per cent. at the Museum, and 10·5 per cent. at the intermediate station of Woodhouse Cliff. On Sundays the loss was less, being 16·8 per cent. at the Museum, and 4 per cent. at Woodhouse Cliff. Truly, here was a reason for calling the first day of the week Sunday. Some would be likely to feel surprise that the practical cessation of manufacturing smoke for above thirty-six hours should not produce a greater improvement in the sunshine of the central station. But, putting aside any preconceived ideas, they must accept the fact that the agencies still operative on Sundays were responsible for 16·8 per cent. of the diminished sunshine. These were, firstly, the natural haze of a valley station with its river; and, secondly, and chiefly, the products of the burning of coal for domestic purposes. They would recognise that the producer of manufacturing smoke had in a large number of cases brought science to his aid in diminishing the amount of unconsumed carbon which he threw into the atmosphere, and that he reaped the reward of this good deed. On the other hand, the householder, with his tens of thousands of fireplaces, had had little done for him in guidance towards the same laudable object. The use of gas as a fuel for domestic purposes might be extended in the future. But much was possible in the arrangements for burning coal for domestic use, and Leeds was justly proud of the contribution to solving the problem made by Mr. T. Pridgin Teale in the fireplaces that bore his name. Accompanying the paper were a number of tables, one of which showed the total amount of sunshine for each day of the week during the ten years. Over-refinement in theorising upon these data, said the authors of the paper, was needless, but the partial improvement of the central station on Saturdays was clear, as was the case on Thursdays, probably due to the Wednesday half-holiday of those tradespeople who must attend to their businesses on the Saturday. It was evident that if the people had more holiday there would be more sunshine. The records of sunshine already given were the results of more than 10,000 observations, and their interest to many would be prospective rather than retrospective. Were they improving or deteriorating? If the same influences operated in the same way, they ought to find that the increase of population and of manufactories during the period would have the effect of making worse what was bad before. The population of Leeds in 1887 might be taken as about 350,000; in 1896 it was assumed to be 400,000. If the atmosphere held its own against this increasing stress and strain it was something to the good. The deficiency at the Museum as compared with Adel for the five periods of two years each was as follows:—1887-88, 24 per cent.; 1889-90, 33·4 per cent.; 1891-92, 30·5 per cent.; 1893-94, 20 per cent.; and 1895-96, 19·3 per cent., or a mean deficiency on ten years of 25·4 per cent. The answer might be considered satisfactory and encouraging. The last two-year period placed the atmosphere of the central station in a better position than any of the preceding two-year periods, and this had occurred in spite of the steady increase of both population and buildings. Whilst regarding these results as encouraging, they felt that their legitimate application was as a stimulus to further endeavours to attain the blessing of a purer atmosphere.

Dr. J. B. Cohen, lecturer in organic chemistry at the Yorkshire College, read a paper on "Air Pollution in Towns." Pure water and wholesome food, he said, had so long been recognised as essential to the general health of the community that they now claimed the strictest supervision on the part of every municipal body. It seemed remarkable therefore that the air, the consumption of which exceeded in weight five times that of liquid and solid food, should be subjected to no more searching test than that furnished by the daily meteorological record, which gave no information as to its purity at all. Yet it was much more important to know the extent of atmospheric pollution than its temperature, pressure, dampness or the direction of its currents, however valuable they might be. For example, it was of more vital interest to ascertain that the number of bacteria on a certain day in February last year in a certain volume of air (5½ litres) was *nil* on Woodhouse Moor and from 5 to 20 in the close courts and slums of the centre of the city; that on another day in July it was 1 on Woodhouse Moor and from 4 to 35 in the same courts in the city; and that on another day in September it was again *nil* on the Moor and from 14 to 96 in the courts. If a daily record was kept of the bacterial condition of the air, in addition to its temperature and pressure, they would have some direct evidence of its purity in different parts of the town, and, granted that the experience of others confirmed his own, they would find that the bacterial conditions would be a fair test of the sanitary condition of the places in question. He had no hesitation in saying that the courts which furnished the higher bacterial numbers should cease to exist in their present condition. Smoke was another source of pollution of a town atmosphere. It seemed to be very little affected by the critical remarks which were constantly being levelled at it. Whether smoke was a necessary evil or not, whether it arose mainly from factory or

domestic chimneys, did not affect the fact that it was a considerable evil. In the atmosphere of Leeds something like 8 cwt. of soot was constantly floating, which was the permanent representation of the 20 tons daily discharged into the air. He doubted whether any one would care to dispute that health was affected by a smoky atmosphere. No one could dispute the fact that the discomfort and dirt arising from the smoke were very great. The only part of the damage which could be measured was the extra outlay for washing. But the amount of the washing bill was an insignificant item compared with the lowered vitality and moral tone of the community. The problems they had to face were how to purify the atmosphere from its bacterial impurities which arose from overcrowding and insufficient sanitary accommodation and from the smoke. Those problems, like that of river purification, were rendered particularly complex, not from any inherent difficulties, but from the fact that long habit and a deplorable want of foresight had shackled them with "vested interests." To begin with, boiler chimneys, which were accountable for much smoke, required some more rigid and intelligent system of inspection. It had been demonstrated that a boiler chimney need not smoke. The present system of inspection, which placed the duty in the hands of the municipal authority, was doomed to failure. Smoke inspectors should be empowered to advise, and the adviser must be a man who knew his business. The domestic hearth was more difficult to deal with. If gas was charged at a rate more nearly approaching its cost, its consumption for heating purposes would be more general. From a careful study of the subject he felt in a position to state that gas fires judiciously used were thoroughly healthy and efficient heating appliances. In conclusion, Dr. Cohen said he wished to claim for air the same attention and rigorous supervision which was now bestowed upon food and water. Under the shadow of a smoke cloud in the closely packed courts which fringed the open drain that custom taught them to call a river, neither a clean atmosphere nor a clean anything else could ever exist.

DUNDEE INSTITUTE OF ARCHITECTURE.

SEVERAL members of the Institute visited Edinburgh on the 18th inst., and with a party representing the Architectural Association of the latter city, drove to a number of places of interest. The McEwan Hall was first visited, and there Mr. Clarke, inspector of works, described the features of the building. The party then proceeded to Blackford Observatory, where the members were received by Professor Copeland and Mr. Ramsay, his assistant. Mr. W. W. Robertson described the circumstances connected with the erection of the observatory, and the Professor and his assistant were awarded a vote of thanks for their descriptions of the contents of the building. Craigmillar Castle was then visited, Mr. Thomas Ross, the president of the Edinburgh Association, conducting the party over the castle and explaining its history. The party proceeded by way of the Queen's Drive to Holyrood, but time did not permit of a visit to the Palace.

ANCIENT RUIN IN MATABELELAND.

MESSRS. T. G. NEALE and George Johnson returned some few days ago from an expedition ranging over a wide stretch of country, which they undertook more for the purpose of exploring and locating undiscovered ruins, than of working those already "pegged out" by the company. The country traversed, says the *Buluwayo Chronicle*, chiefly in the north, embraced the lower Shangani, the lower Umvumque, the lower Sebakwe, the lower Gwelo, and the lower Inyati districts, most of these being unexplored before in search of ruins. In all Messrs. Neale and Johnson located more than eighty-five new ruins, and one of them appears to be unique and of quite exceptional interest from an archaeological point of view, as it differs entirely from any known to the discoverers, and they speak from a knowledge of upwards of 200. In shape alone this ruin resembles the celebrated Zimbabwe ruins, but the walls, which are perfectly intact, about 15 inches thick and 15 feet high, seem to be made in a different way and of a new form of masonry. They do not consist of either bricks or tiles, but appear in one solid piece of glazed material, as if burned after they were erected in position. If this impression of the discoverers is borne out on re-examination, then we have a new method and material of building hitherto alien to the country and probably to be referred to a different race of people from the ordinary ancient workers. The ruin shows the remains of a well-shaped doorway and also, which is an unusual feature, an aperture about 4 feet high and 3½ feet wide placed some distance up the wall and which was without doubt a window. Altogether, the ruins are a proof that the original inhabitants were a people who had attained a high standard of excellence in the art of building. Some fine gold was found in the debris, but Messrs. Neale and Johnson were

unable to properly explore the ruin owing to its distance from water. The tradition that there exists an extraordinary ruin in the country, the building of which still has in position massive stone doors, and which is regarded with superstition by the few natives who know of it and whose doors have never been opened, Messrs. Neale and Johnson heard sufficient evidence of to regard as an actual fact, but owing to its being situated in a very unhealthy district they have had to postpone visiting it for the present. The explorers, it may be worth stating, found the natives perfectly submissive, and Somabula, with whom they had some conversation, said the idea of a rising was over.

READING NEW POST OFFICE.

THE postal needs of Reading having outgrown the accommodation, a new building has been erected in Blagrove Street, near the Board School offices, and adjoining the stable entrance of the Queen's Hotel, and is thus as near as possible to the railway stations—a great advantage, seeing that the main object of its construction is to free the headquarters of the enormous parcel traffic and the letter-sorting. Henceforth all the carts and letter and parcel carriers will start from the new office, and the traffic of the up and down road coaches and also from the stations will go direct through the new premises.

The new building is carried out in local red brick, with Bath stone dressings and rough grey granite bases for the main columns, with glazed bricks running shoulder high. Inside the utmost has been made of the site, and a notable feature is the ample daylight afforded to every part. For night work what appears to be almost an excessive number of gas pendants and brackets have been placed. An excellent feature is the heating, which is fed by a boiler in the basement. The ground floor is occupied by the large rooms required by the parcels and letter sorters, who number over 100, and the postmaster's comfortable private office. The arrangement of the basement includes a fine storage room, fitted with a lift for raising and lowering baskets, &c., commodious and well-lighted kitchens for clerks and also for letter-carriers, each provided with roomy and well-fitted ranges and other appliances, and excellent lavatories. The foundations and also the walls are of such strength that as the town and its business grow an upper storey can be added at will.

The work has been very satisfactorily carried out from plans prepared by the Office of Works by Mr. Tucker, of Reading, the contractor, under the careful supervision of Mr. Askew, of the Office of Works.

BIRMINGHAM NEW TELEPHONE EXCHANGE.

TO meet the rapidly increasing demands on the means of telephonic communication in Birmingham it has been expedient, indeed necessary, to erect a new exchange of imposing dimensions at the corner of Newhall and Edmund Streets. The site has an area of about 830 square yards, with a frontage to Edmund Street of about 35 yards and to Newhall Street of about 25 yards. The building, which is of four storeys (basement, ground floor, and first and second floors), is in a modern Renaissance style, and is executed in Ruabon red brick and terra-cotta. The façade is divided by bold piers, with highly decorative treatment of the upper portion, which consists of arches and gables ornamented with a profusion of moulded terra-cotta. A number of the windows, including those at the corner, stand forward as bold bays from a deeply-arched recess, and are set off with terra-cotta balustrades. The upper portions of the piers are embellished with a flat fretwork design in sunk panels, which contrasts with the high relief floral embellishments of the arches and spandrels. At the top of the façade there is an open balustrade of terra-cotta, broken by the gables and by small pinnacles. Some of the principal gables are decorated with large floral medallions, and are surmounted by an open tracery, while others are pierced by the chimneys, which, owing to the internal arrangements, were required to be carried up the outer walls of the structure. The chimneys have, therefore, been made a portion of the decorative scheme. The main entrance to the building is through a wide arched doorway, guarded by elaborate wrought-iron gates, in Newhall Street. In the basement, which is practically on a level with Edmund Street, apartments have been fitted up for the caretaker, the local staff and the local manager. There is, moreover, a call office, which, when opened, will be a great convenience to the public; and adequate accommodation has been provided for the carpenters, the wayleave men, the faultsmen and fitters, the electrical inspectors and the engineering inspectors. Access to these rooms will be obtained from an entrance in Edmund Street, an entrance which will also be used by the operators. Upon the first floor Mr. Coleman and Mr. Cotterill have their offices, ample provision being made for the district manager's staff, and for all who have business to trans-

act in that department. The second floor is mainly devoted to the "exchange" or switch-room, an extensive apartment 104 feet in length and 40 feet in width. As, however, the whole of the room will not be required at present a portion has been partitioned off as a dining and retiring room for the lady operators. Adjoining the switch-room is the test-room, and beyond this are the cable shaft and a useful lift, while adequate cloak-room and lavatory accommodation has been provided, together with a private staircase leading to the entrance in Edmund Street. A kitchen and scullery have been fitted up, so that the operators may have their meals on the premises on the co-operative principle. The building has been made fire-proof; the rooms are to be illuminated by electricity; they are admirably lighted, well ventilated and warmed.

The building, which was designed by Messrs. Martin & Chamberlain, and erected by Mr. Thomas Rowbotham, is now complete, and forms an important addition to the group of handsome structures in Edmund Street and Newhall Street.

TESSERÆ.

The Cathedral of Verona.

IN regard to the cathedral of Verona antiquaries have much disputed. It was certainly completed by A.D. 806, and the epitaph to an archdeacon, Pacificus (who founded seven churches in the city, and was himself a skilful artist in wood, stone and metal), tells that he ordered repairs thirty years after the death of Charlemagne, namely, 844. The apse and lateral walls near the chancel may be of the original structure, otherwise this grand and characteristic building cannot be referred, in any part, to date earlier than the twelfth century. A genuine and still intact specimen of the ninth century is the crypt of St. Zeno, founded to contain the tomb of that saintly Bishop of Verona, by Pepin, King of Italy. With low semicircular vault, supported by forty columns irregular in their shafts and capitals, this sole remnant of the original church embodies an idea yet new in Italian architecture; and a mysterious gloom, a brooding presence of antiquity, give most impressive effect to those dim aisles and crowded pillars under its low-arched roof. As to the architects of this period little is known, except that the Comasque builders still retained the pre-eminence and privileges they had enjoyed under the Longobard kings, confirmed to them by Charlemagne, with exemption from all local statutes and burdens; and like favour being extended towards them by the popes, they were allowed to fix their own wages, while practitioners not of their society were forbidden to enter into rivalry against them.

Giotto.

If, as is asserted, the Middle Ages centre in Dante, they centre also in Giotto, his friend and companion, scarcely his inferior in power. He is the first of the universal artists, who were perhaps goldsmiths, architects, engineers, engravers, sculptors and painters in all vehicles, who could design cathedrals and paint frescoes on their own walls, like Leonardo, or Dürer, or Michel Angelo. Cimabue was nobly born and attained notice and influence early. His advance in all before him is marked. But the best thing he did was to discover, and value and educate to surpass himself the shepherd's boy whom he found one day drawing a ram's head on a tile in the hill pastures that look down on Valdarno. Giotto's chief works are at Padua and Assisi; some remain at Rome, and at Ravenna one of the most beautiful contrasts in the world is in St. Giovanni Evangelista, where one of the chapels is ornamented like the Arena at Padua with Giotto's blue backgrounds and lovely faces, and the solemn mosaics of the roof are all in Syrian purple and sea green. His greatest architectural monument is the Campanile at Florence; the Arena Chapel at Padua gives an idea of the universality of his powers. He was very ugly or irregular of feature, and seems to have enjoyed the circumstance greatly. He never left off making jokes, great and small. A century of Giotteschi, or disciples of his, succeeded him before any one again reached the mark he had made. Orcagna is the next to do so. As a colourist, to this day no man has excelled or can excel the qualities of the blonde faces one sees at Padua and Ravenna. His blues, warm whites, golden tints on hair and ornament, with many subtle uses of Indian red and other pigments and various greens, are all matter of professional study to this day.

James Prinsep.

Although he lived for no more than forty-one years, James Prinsep must always be classed among the earliest and most enthusiastic of English archaeologists in India. His versatility was remarkable. At his death in 1840 he was assay master in the Mint at Calcutta, where he succeeded Professor Wilson in 1833. He was an excellent assayist and analytical chemist, and well acquainted with almost every department of physical science; a draughtsman, an engraver, an architect and an

engineer, and one of the most profound and learned orientalists of his age. In 1828 he communicated to the Royal Society a paper on the "Measurement of High Temperatures," in which he described, amongst other ingenious contrivances for ascertaining the order, though not the degree, of high temperatures, an air thermometer applicable for this purpose, and determined by means of it, probably much more accurately than heretofore, the temperature at which silver enters into fusion. His activity while resident at Benares has more the air of romance than reality. He designed and built a mint and other edifices, he repaired the minarets of the great mosque of Aurengzebe, which threatened destruction to the neighbouring houses; he drained the city and made a statistical survey of it, and illustrated by his own beautiful drawings and lithographs the most remarkable objects which the city and its neighbourhood contains; he made a series of experimental researches on the depression of the wet-bulb hygrometer; he determined from his own experiments the values of the principal coins of the East, and formed tables of Indian metrology and numismatics, and of the chronology of the Indian systems and of the genealogies of Indian dynasties, which possess the highest authority and value. When transferred to Calcutta he became the projector and editor of the "Journal of the Asiatic Society of Bengal," a very voluminous publication, to which he contributed more than 100 articles on a vast variety of subjects, but more particularly on Indian coins and Indian palæography. He first succeeded in deciphering the legends which appear on the reverses of the Greek Bactrian coins, on the ancient coins of Surat and on those of the Hindoo princes of Lahore and their Mohammedan successors and formed alphabets of them by which they can now be readily perused. He traced the varieties of the Devanagari alphabet of Sanscrit on the temples and columns of Upper India to a date anterior to the third century before Christ, and was enabled to read on the rocks of Cuttock and Gujarat the names of Antiochus and Ptolemy and the record of the intercourse of an Indian monarch with the neighbouring princes of Persia and Egypt; he ascertained that, at the period of Alexander's conquests, India was under the sway of Buddhist sovereigns and Buddhist institutions, and that the earliest monarchs of India were not associated with a Brahminical creed or dynasty. These discoveries which throw a perfectly new and unexpected light upon Indian history and chronology and which furnish, in fact, a satisfactory outline of the history of India from the invasion of Alexander to that of Mohammed Ghori, a period of fifteen centuries, are only second in interest and importance, and, we may add likewise, in difficulty, to those of Champollion with respect to the succession of dynasties in ancient Egypt. These severe and incessant labours in the enervating climate of India, though borne for many years with little apparent inconvenience or effect, finally undermined his constitution, and he was at last compelled to relinquish all his occupations and to seek for the restoration of his health in rest and a change of scene. He arrived in England, but the powers both of his body and mind seem to have been altogether worn out and exhausted, and he only lingered for a few months among his countrymen.

Italian Villas.

There are in Italy, and particularly in Rome, a vast number of charming habitations which, under the most simple forms, bear the stamp of a refined taste, and prove to the attentive architect that credit may be obtained in bestowing care upon the most humble production, and this reflection should be a consolation to those who profess an art, in which a very rare combination of fortunate circumstances can alone furnish the opportunity of being entrusted with the execution of great works. If such men as Bramante, Vignola, Palladio, Sangallo and Peruzzi have discovered in antiquity models for the buildings which they have erected, if these successful practitioners of the art have known how to apply even in their slightest works such admirable distribution, so agreeable an arrangement of parts, that refinement, too, which constitutes the great charm of their works, why should we not when similarly circumstanced endeavour to emulate them? It is with the liveliest feelings of interest that we behold the great artists whom we have just mentioned bestowing upon the simple habitation of the citizen the same degree of spirit, care and refinement of taste which they have manifested in the erection of temples and sumptuous edifices. They have embellished everything, and their pencils have thrown a charm over the modest retreat of the philosopher in no way inferior to that of the palace of the prince. Penetrated with the importance of their art, they have taught us how to rid it of the prejudices of routine and the extravagances of caprice, they have taught us to take nature for our guide and her imitators for our models, and have in some measure restored architecture in bringing back the art to its true intent. We ever perceive them skilfully availing themselves of the peculiarities of the site, and fulfilling with admirable address the various requisites of the design. Manifesting ingenuity even in the minutest detail, they never appear to have worked at random; they

seem to have felt that nothing could be considered beautiful in architecture which was not authorised by some recognised utility; that true genius did not consist, as some moderns have thought, in waging war with reason to create novelties and produce bizarre effects, but rather in the art of successfully applying the means which nature points out, which the site furnishes and which the work in hand demands. It is in thus fulfilling these conditions that they have succeeded in imparting to each work its proper character, and it is thus that, ever guided by good taste, they have been enabled to make us lose sight even of the very difficulties they had to combat. Indeed, the greater part of their works bear the impress of that rare simplicity which, like some revealed truth, always appears so intelligible to those to whom it is disclosed. Their buildings are picturesque without being confused, possess symmetry but are not monotonous, and being carefully executed frequently unite, to express ourselves in terms of art, the freedom of the sketch with the precision of the more finished performance. We contemplate, with unceasing admiration, the ingenuity displayed in the application of the various materials, such as marble, stone, brick, wood, &c., few examples of which are to be found elsewhere.

Greek and Christian Art.

To an artist, merely as a man who delights in seeing and recording natural beauty, the great difference between Greek and modern Anglo-Christian life would be that art and nature met in Greek life, and do not meet in ours. The Greek saw enough of beauty to know how much it is worth. Our life, artistically speaking, is a continual struggle against ugliness. An Athenian's life is described, not untruly, as a continual, rejoicing, unreflective embrace of beauty. Ugliness he had, and absurdities, and his eye was quick to note them. Aristophanes's sketch of the fat man in the torch-races, blown and incapable, may perhaps be remembered by some of us, with many others (as the poet, the sycophant and the messenger gods in the comedy of the "Birds"). But every citizen of Athens lived continually out of doors—"for ever delicately marching through transparent liquid air"—in the finest atmosphere on earth. He saw Hymettus and Pentelicus, and Ægina and Salamis in distance, though it is true he considered Ægina "an eyesore." He saw Athena and Theseus, the forms of his gods and heroes, all around him, and he saw daily the living frames of strength and beauty from which the great statues were conceived. The Greek was his own model and type; he idealised man because he really knew the beauty of man. He thought the beginning and end of art was to set forth or represent his gods and himself, which was well; and he thought his gods must first be like himself, which was not so well. He surrounded himself and his heroes with beauty, subject and auxiliary to his own beauty, exactly as the Goth carved flowers round the niches which held the statues of his saints. He studied animals, the horse in particular, as his companions (one cannot attach much importance to Myron's celebrated cow), considering himself the fairest of all animals. Accordingly he seized on animal character with success when he tried. Greece, as Mr. Maurice said long ago, and as every one says now, represents to us the power of the man, of the human soul unconscious of the Divine teaching which is yet with him—not taught to look beyond himself—and contented with the glorious things within his reach, and poetry and plastic art were the most glorious of these things. His art, then, was the natural expression of an excusable self-admiration or self-respect.

Etruscan Art.

Strength, no less than delicacy and grace, were among the qualities that distinguished the arts of the Etruscan nation, who cultivated with success all the arts that embellish life. The minds that could conceive and the hands that could execute the admirable designs on the Etruscan vase with that wondrous precision, delicacy and beauty, were not thereby rendered incapable of constructing great architectural masses—the Cloacæ or the Cyclopean wall. Volterra, Cortona and other cities speak through their many-sided stones. The Cloaca Maxima is in these great days of constructive science not deemed a mean exhibition of architectural intelligence; while their cavern-hewn sepulchres, with their monolith portals, are additional evidences of that universal feeling pervading the human breast, of perpetuating the memory of the dead through the agency of art. No fancy can hope to estimate and no powers describe the extent of their artistic acquirements. Mystic mirrors, whose purposes have excited the conjecture of the antiquary, testify to the engraver's talent; no object and no purpose were beneath the attention of the artist, and all were alike elevated into importance by the skill with which he endowed them. The subjects often appear of the most inconsistent character as decorations for the chambers of the departed. Scenes of festivity and mirth, the Symposium and the Dance, are intended to represent the enjoyment of the soul in another state of existence; and their only idea of its future happiness was through the means which during life the deceased person enjoyed. For as the materiality of the soul constituted a con-

dition of belief, a reference to their previous modes of life and a beatification of it expressed their idea of a future state. Nor were there wanting more serious and gloomy views, as is exemplified by the Medusæ and monsters, with demons, genii, furies and the whole tribe of revengeful personifications. These terrific agencies are contrasted by some of the most exquisite combinations of animal and vegetable forms, which, if we have now lost their mystic significance, remain as examples for decorative purposes worthy of our emulation. Far distant epochs, different tastes and ideas of pecuniary cost, may explain varieties of style. Thus, while Veii affords specimens of animal-painting of rude but archaic interest, *The Chamber of the Boar-Hunt at Corneto*, from its incontestably genuine Hellenic design, is allowed to be one of the most instructive examples of pictorial art in Etruria. Though they have existed on some of the tombs for more than 2,000 years, the colours on the stucco are wonderfully brilliant, and "as fresh," says Mr. Dennis, "as when first laid on." Instances might be multiplied, but it is sufficient to add that through the instrumentality of the art of painting (though we know so little of their language) we are able to learn more of the Etruscan religious belief, their poetical views of the transit of souls into unseen worlds, and their various conditions when arrived there, than from any other source.

Palladio.

Palladio is to be admired for his daring and originality, for his starting up in the midst of error, when art began to grow fanciful and trifling, for his care in shunning the evils of his time and borrowing from the beauties of the past. To test Palladio too severely by the models of antiquity is unfair and impossible, because the modification and change necessary to the structure destroy the parallel. To test, too, Palladio by the mean experiment of subordinate variations is ungenerous, because Roman architecture itself imposed with its parts much more than it charmed by its minutiae. Palladio's great achievement, too, was the adaptation of the orders to domestic habitations in which antiquity became subservient, and in which the whole array of detail was subsidiary. One great reason why many condemn Palladio is because he leads them occasionally into error, and too loosely scatters his decoration. Tell them of a palace or a church designed by him, and they will tell you of an incorrect member or a broken tympanum; or speak to them of originality, and they will shout for a precedent. The source of beauty, however, may have been misunderstood, and the elements of grandeur may have been mistaken. Beauty belongs to no particular form, but to the harmony of relations blending in that form, and the same principles which adjusted the lovely outlines of antiquity may enter into the composition of larger and grander objects.

GENERAL.

A Memorial of the late Bishop of Wakefield is to be erected in St. Mark's Church, Noel Park, N.

Turner's Cottage, Sandycombe Lodge, Twickenham, was sold on Tuesday for 1,200*l.*, or about eighteen years' purchase at present rental.

A Committee, consisting of Messrs. Anderson, M'Laren, Page and Stewart, has been appointed to make arrangements for the formation of an Architectural Association in Perth.

M. Blondel, one of the ablest of the Paris architects, died last week in his seventy-sixth year. Among his late works is the Bourse du Commerce.

A Stained-glass Window, the subject of which is "Christ blessing little Children," has recently been inserted in Emmanuel Church, Lockwood, Huddersfield, by Miss Shaw, of Torquay, in memory of her late father and mother, Mr. and Mrs. Bentley Shaw, of Lockwood.

St. Clement's Church, Liverpool, was reopened on Sunday, the 19th inst. The ventilating and heating apparatus has been renewed; walls painted warm stone colour, the pews, woodwork and fittings have had the old paint burnt off and been repainted, grained (light oak) and varnished; pillars painted and finished in red granite with suitable gold capitals and bases; and the body of the church has been fitted with incandescent light.

Mr. George Carrick, a member of the firm of Welchman, Carrick & Jackson, solicitors, of Wisbech, Cambridgeshire, has just been elected town clerk of that borough. Mr. Carrick is the eldest son of the late Mr. Joseph Carrick, of Wigton, and commenced practice in Wisbech about twenty years ago.
